CHAPTER 6

BLOOD AND HEMOPOIESIS

GENERAL CONCEPTS

I. In humans, the average blood volume is 5 liters, constituting 7% of the body mass.

II. Blood is a specialized fluid connective tissue consisting of cells and cell fragments (46% of blood volume) floating in a unique liquid extra-cellular matrix (54% of blood volume).

III. Functions

A. Delivery of nutrients and oxygen to cells and tissues

B. Transport of wastes and carbon dioxide away from cells and tissues

C. Delivery of hormones and other regulatory substances to and from tissues

D. Maintenance of homeostasis by acting as a buffer

E. Thermoregulation

F. Transport of cells of the immune system

IV. Components

A. Cells and cell fragments

1. **Red blood cells (erythrocytes, RBCs)**, produced in the bone marrow

2. **White blood cells (leukocytes, WBCs)**, produced in the bone marrow; some lymphocytes are also produced in lymphoid tissues and organs.

3. **Platelets**. Cell fragments derived from **megakaryocytes** in the bone marrow; contain granules and function in blood coagulation; 150,000-450,000 per microliter blood

B. **Plasma**. Constitutes the extracellular matrix of blood

1. Composed of 90% water and 8-9% protein.

a. Major protein components (plasma proteins)

i. Albumin. Main protein component of plasma, synthesized in the liver. Establishes colloid osmotic pressure within vessels and acts as carrier protein for hormones, metabolites and drugs.

ii. Globulins. Includes gamma globulins which are antibodies secreted by plasma cells.

iii. Fibrinogen. Fiber precursor protein, which is converted into fibrin when blood clots.

2. **Serum**. Yellowish fluid remaining after blood has clotted.

RED BLOOD CELLS

I. Cells resemble bi-concave discs, 6-8 microns in diameter; 4-6 million per microliter of blood

II. Cells are non-nucleated. Cytoplasm contains hemoglobin and cytoskeletal elements but lacks other organelles.

III. Transport oxygen and carbon dioxide

WHITE BLOOD CELLS *(images)*

I. White blood cells are transported in the blood and migrate through vessel walls (diapedesis) to become active in connective tissues; 5-10 thousand per microliter of blood.

II. **Granular leukocytes**

A. **Neutrophil (polymorphonuclear leukocyte, PMNs)**

1. 46-81% of circulating WBCs

2. Spherical cell, 12-15 microns in diameter; pale or unstained cytoplasmic granules; heterochromatic nucleus with three to five lobes

3. Move from the blood to sites of infection

4. Phagocytose bacteria and debris

B. **Eosinophil**

1. 1-3% of circulating WBCs

2. Spherical cell, 12-15 microns in diameter; cytoplasmic granules stain with eosin; bi-lobed nucleus

3. Move from the blood to sites of infection

4. Secrete proteins cytotoxic to parasites, neutralize histamine, and internalize antigen-antibody complexes

C. **Basophil**

1. <1% of circulating WBCs

2. Spherical cell, 12-15 microns in diameter; cytoplasmic granules stain dark blue with hematoxylin; nucleus with 2-3 lobes

3. Similar to mast cells; participate in the hypersensitivity reaction by secreting histamine and heparin

III. **Agranular leukocytes**

A. **Lymphocyte**

1. 24-44% of circulating WBCs

2. Spherical cell, 6-8 microns in diameter; scant cytoplasm and a round heterochroma tic nucleus often with a small indentation

3. T and B lymphocytes

a. **T lymphocytes**. Originate in the bone marrow and mature in the thymus; provide cell-mediated immunity

b. **B lymphocytes**. Originate in the bone marrow and are carried in the blood to lymphoid tissues and organs, where they become activated and proliferate, transform into plasma cells in connective tissue, and provide humoral immunity by secreting antibodies

B. **Monocyte**

1. 3-7% of circulating WBCs

2. Large spherical cells, 12-18 microns in diameter; abundant cytoplasm stains gray-blue; large, U-shaped, euchromatic nucleus.

3. Enter connective tissue, where they transform into macrophages; function in phagocytosis and antigen presentation

HEMOPOIESIS *(images)*

I. General considerations

A. Hemopoiesis is the process of blood cell formation, beginning with a pleuripotential stem cell that subsequently goes through a series of cell divisions and differentiation stages to produce all the mature blood cells.

B. During fetal life, blood cells are first produced in the yolk sac, followed by the hepatic phase when blood cells, mostly erythrocytes, are produced in the liver. The third or bone marrow phase begins during the second trimester and continues until birth.

C. Postnatal hemopoiesis occurring in red bone marrow located in the spongy bone region of long bones, vertebra, ribs, sternum, and the skull, produces erythrocytes, granular leucocytes, B lymphocytes, monocytes and platelets. Lymphocytes are also generated in lymphoid organs and tissues.

D. Blood cells have a relatively short life span and, therefore, new cells are formed continuously.

E. Precursor cell lineage

1. **Stem cells**. Pleuripotential cells that give rise to all the blood cells; divide both to renew their own cell population as well as to form progenitor cells, thus beginning the process of blood cell formation. Hemopoietic stem cells generate two major lineages, **myeloid** and **lymphoid**. Cells of the myeloid lineage consist of erythrocytes (erythropoiesis), granulocytes composed of neutrophils, esosinophils and basophils (granulopoiesis), monocytes (monocytopoiesis) and megakaryocytes (thromopoiesis). The lymphoid lineage includes B and T lymphocytes (lymphocytopoiesis)

2. **Progenitor cells**. Less potentiality than stem cells; committed to the formation of just one or two blood cell lines; have high mitotic activity, dividing to reproduce self and to form precursor cells.

3. **Precursor or blast cells**. Begin morphologic differentiation; display characteristics of the mature blood cells they will form; not self-renewing

4. **Mature blood cells**. Form after several cell divisions of the precursor or blast cells

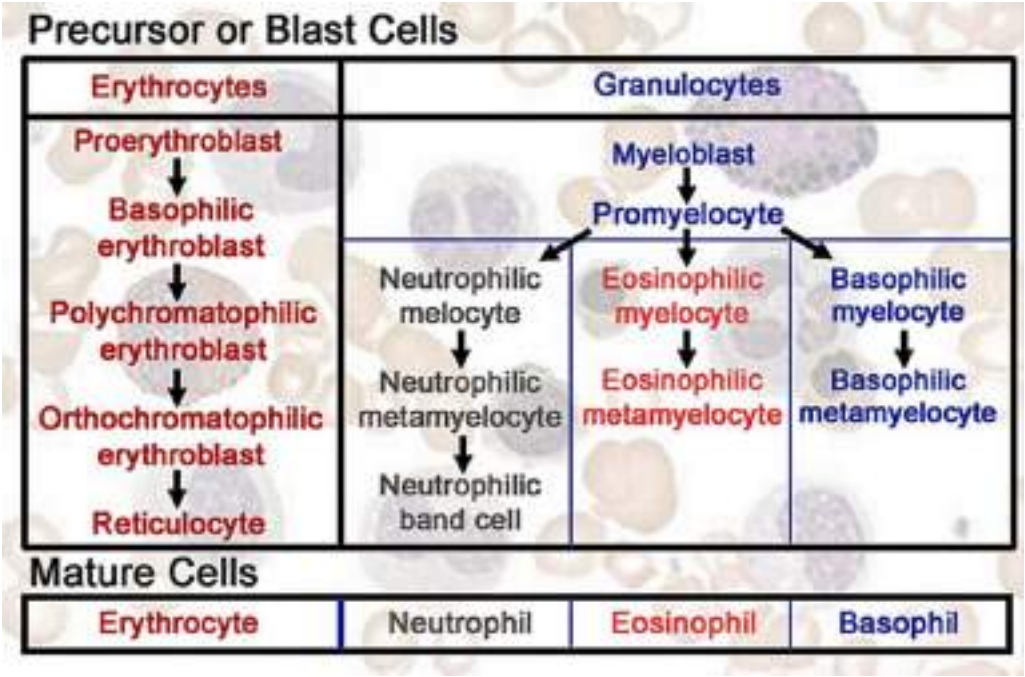

Figure 6.1. Hemopoiesis

II. **Erythropoiesis**: Formation of erythrocytes ***(images)***

A. Process that results in a non-nucleated cell filled with hemoglobin and specialized for transporting respiratory gases

B. Stages. Cells listed in the order in which they form

1. **Proerythroblast**. Precursor cell

2. **Basophilic erythroblast**. Increased numbers of polyribosomes for hemoglobin production results in strong cytoplasmic basophilia; nucleus possesses a "checker-board" chromatin pattern typical of differentiating erythrocytes. The first stage of erythropoiesis that is readily identifiable.

3. **Polychromatophilic erythroblast**. Number of polyribosomes is reduced as hemoglobin accumulates, resulting in the grayish-stained cytoplasm. No further cell division occurs beyond this stage.

4. **Orthochromatophilic erythroblast (normoblast)**. Smallest cells in the series. Continues condensation of the nucleus; increased eosinophilia of the cytoplasm due to accumulating hemoglobin. Nucleus is small, round and very heterochromatic. Late in this stage, the cell extrudes its nucleus.

5. **Reticulocyte**. Non-nucleated cell; small number of polysomes form a reticular

network giving the cytoplasm a lilac color. The polysomes and any other organelles are degraded within one day of release forming mature erythrocytes. In normal blood, reticulocytes constitute about 1% to 2% of the total circulating red cells.

6. **Mature erythrocyte**. Biconcave shape which increases the surface to volume ratio, critical for gas exchange. Erythrocytes transport oxygen and carbon dioxide and remain in the blood for about 120 days.

III. **Granulopoiesis**: Formation of granulocytes ***(images)***

A. Process by which cells first produce nonspecific, azurophilic granules (lysosomes) and then synthesize specific granules containing proteins unique for each granulocyte cell type.

B. Stages. Cells listed in the order in which they form

1. **Myeloblast**. Precursor cell

2. **Promyelocyte**. Earliest identifiable stage. Large euchromatic nucleus. Produces azurophilic (blue) granules that contain lysosomal enzymes

3. **Myelocyte**. Nuclear condensation and the appearance of cell-specific granules containing proteins unique for each of the granular leukocytes. Azurophilic granules still present.

4. **Metamyelocyte**. Cell-specific granules continue to accumulate and the nucleus changes morphology to resemble that of the mature cell. No further cell division after this stage.

5. **Band or stab cell**. Nuclear indentation creates a horseshoe-shaped or band-shaped nucleus. Most apparent in the neutrophilic cell line.

6. **Mature neutrophils, eosinophils, and basophils**. Characterized by lobulation of the nucleus and presence of specific granules unique to each cell type.

IV. **Monocytopoiesis**: Formation of monocytes

A. **Monoblast**. Precursor cell

B. **Promonocyte**. Large cell, up to 18 microns in diameter; nucleus becomes indented and the cytoplasm is basophilic with numerous fine azurophilic granules (lysosomes).

C. **Mature monocyte**

V. **Thrombopoiesis**: Formation of platelets (thrombocytes) **(images)**

A. **Megakaryoblast**. First recognizable cell, resembles a monoblast.

B. **Promegakaryocytes**. Undergo endomitosis, a process where chromosome replication occurs but neither nuclear nor cytoplasmic division follows. Produces polyploidy cells, up to 64N.

C. **Megakaryocytes** are large cells (50-70 microns) with a highly polymorphic nucleus.

D. **Platelets**. Membrane bound cytoplasmic fragments pinched off from the surface of megakaryocytes that aid in blood clotting.

VI. **Lymphocytopoiesis**: Formation of lymphocytes

A. **Lymphoblast**. Precursor cell

B. **Pro-lymphocytes**. Reduction in size from lymphoblast; some remain in the bone marrow to produce B lymphocytes, others leave the bone marrow and travel to the thymus, where they complete their differentiation into T lymphocytes.

BONE MARROW

I. All spaces within bones contain marrow tissue, a specialized connective tissue.

A. **Red marrow**. Blood forming (hemopoietic) red marrow

1. Present in all bone spaces at birth.

2. Converts to yellow marrow with age. Red marrow persists in the pelvic bones, sternum, skull, ribs, and scapulae, as well as in vertebrae. Also occupies the marrow spaces at the proximal ends of long bones such as the femur and humerus.

B. **Yellow marrow**. Fat storage

II. Red marrow releases blood cells and platelets into the circulation throughout life.

CHAPTER 10

CARDIOVASCULAR SYSTEM

GENERAL CONCEPTS

I. Continuous tubular system for transporting blood, carrying oxygen, carbon dioxide, hormones, nutrients, and wastes

II. Components of the circulatory system

A. **Heart**. Highly modified, muscular blood vessel specialized for pumping the blood. Composed of two atria and two ventricles.

B. **Closed circuit of vessels**. The vessels are listed below in the order that blood would follow as it leaves the heart.

1. **Elastic arteries** *(e.g.,* aorta and pulmonary arteries)

2. **Muscular arteries** (remaining named arteries)

3. **Small arteries and arterioles**

4. **Capillaries**

5. **Venules and small veins**

6. **Medium veins** (most named veins)

7. **Large veins** *(e.g.,* venae cavae, return blood to the heart)

III. Circuitries of the circulatory system

A. **Pulmonary circulation**

1. Circuit of blood between the heart and lungs

2. Blood leaves the right ventricle of the heart through the **pulmonary arteries** and proceeds through a series of smaller arteries to supply **pulmonary capillaries** in the lungs. Blood returns through a series of increasingly larger veins to the **pulmonary veins** to the left atrium.

3. Functions for exchange of carbon dioxide and oxygen between the blood and atmosphere

B. **Systemic circulation**

1. Circuit that distributes blood from the heart to the body tissues

2. Blood leaves the left ventricle of the heart through the **aorta** and proceeds through a series of smaller arteries to supply **systemic capillaries** throughout the body. Blood returns through a series of increasingly larger veins via the **superior and inferior venae cavae** to the right atrium.

3. Functions for exchange of carbon dioxide and oxygen, and nutrients and metabolic wastes between the blood and tissues; distribution of hormones.

C. **Lymphatic circulation**. Consists of a system of blind-ended lymph vessels positioned throughout the body, which return tissue fluid to the venous circulation.

BASIC STRUCTURAL ORGANIZATION *(images)*

I. The walls of the entire cardiovascular system, consists of three concentric layers or tunics that are continuous between both the heart and vessels. The constituents and thickness of these layers vary depending on the mechanical and metabolic functions of the vessel.

II. **Inner tunic**

A. In the heart, this layer is called the **endocardium**; in vessels, it is termed the **tunica intima**.

B. Composition

1. Simple squamous epithelium ***(endothelium)***

2. Varying amounts and types of connective tissue

3. In the largest vessels, longitudinally oriented smooth muscle may be present in the connective tissue layer.

III. **Middle tunic**

A. In the heart this layer is composed of cardiac muscle and is called the **myocardium**.

B. In vessels this layer is composed of circularly oriented smooth muscle or smooth muscle plus connective tissue and is called the **tunica media**.

IV. **Outer tunic**

A. In the heart, this layer consists of a serous membrane, called the **epicardiuim (visceral pericardium)** composed of connective tissue covered with a simple squamous epithelium (mesothelium).

B. In vessels, this layer is called the **tunica adventitia** and is composed of connective tissue; variable amount of longitudinally arranged smooth muscle is present in this layer in the largest veins.

C. Possesses blood vessels that supply the wall of the heart or larger blood vessels

1. **Coronary blood vessels**. Supply the heart wall

2. **Vasa vasorum**. Consists of a system of small blood vessels that supply the outer wall of larger vessels

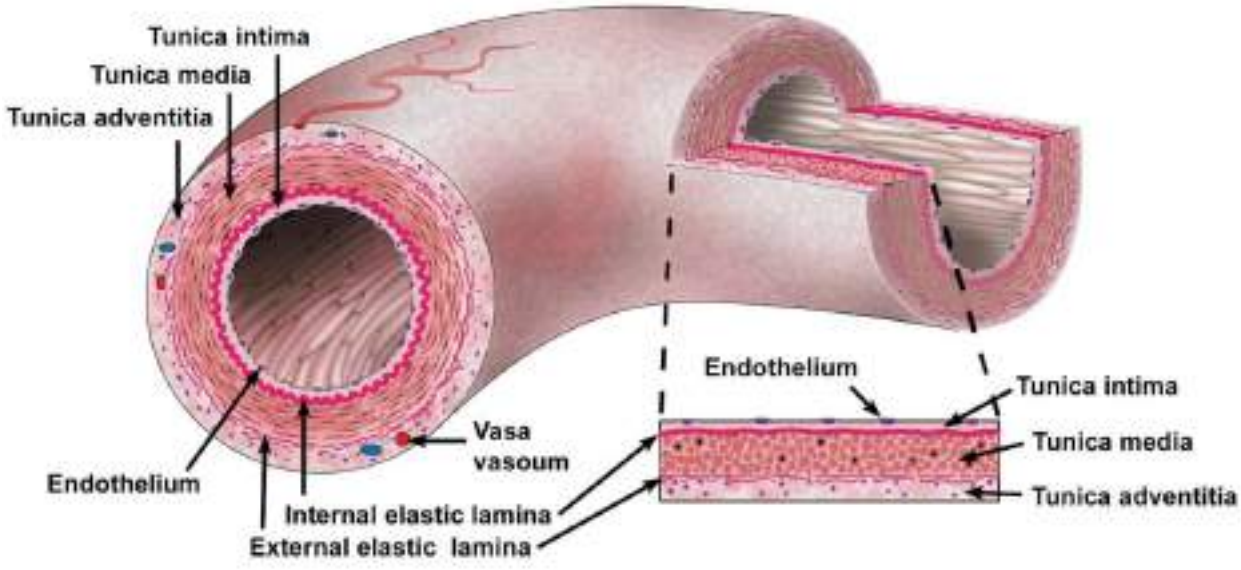

FIGURE 10.1. Structure of a muscular artery.

ARTERIES *(images)*

I. General considerations

A. Carry blood away from the heart and toward capillary beds

B. Have thicker walls and smaller lumens than veins of similar size

C. Tunica media is the predominate tunic.

D. Cross-sectional outlines are more circular in arteries than in veins.

II. Types (Only features distinct to each type and different from the Basic Structural Organization are presented)

A. **Elastic (large) arteries (aorta, pulmonary arteries)**

1. **Internal elastic lamina** in the tunica intima adjacent to the tunica media, is present but difficult to distinguish from the elastic tissue of the tunica media.

2. Tunica media is composed of fenestrated sheets of elastic tissue **(elastic lamellae)** and smooth muscle

3. Passively maintain blood pressure by distension and recoil of the elastic sheets

B. **Muscular (medium, distributing)** arteries

1. **Internal elastic lamina**. Prominent, single, fenestrated, elastic sheet located at its border with the tunica media.

2. Tunica media is composed of smooth muscle.

3. **External elastic laminae**. Consists of fenestrated elastic sheets at the junction of the tunica media and tunica adventitia.

4. Regulate blood pressure and blood distribution by contraction and relaxation of smooth muscle in the tunica media

C. **Small arteries and arterioles**

1. Less than 200 microns in diameter

2. Small arteries have an internal elastic lamina and up to eight layers of smooth muscle in the tunica media.

3. Arterioles usually lack an internal elastic lamina and have one to two layers of smooth muscle in the tunica media.

4. Arterioles are the vessels that regulate blood pressure and deliver blood under low pressure to capillaries.

CAPILLARIES

I. General considerations

A. Site of exchange of metabolites, wastes and gases between the vascular lumen and extravascular tissue.

B. Lumen is approximately 8 microns in diameter, thus only large enough for RBCs to move through in a single row.

C. Composed of the endothelium (simple squamous epithelium) and its underlying basal lamina

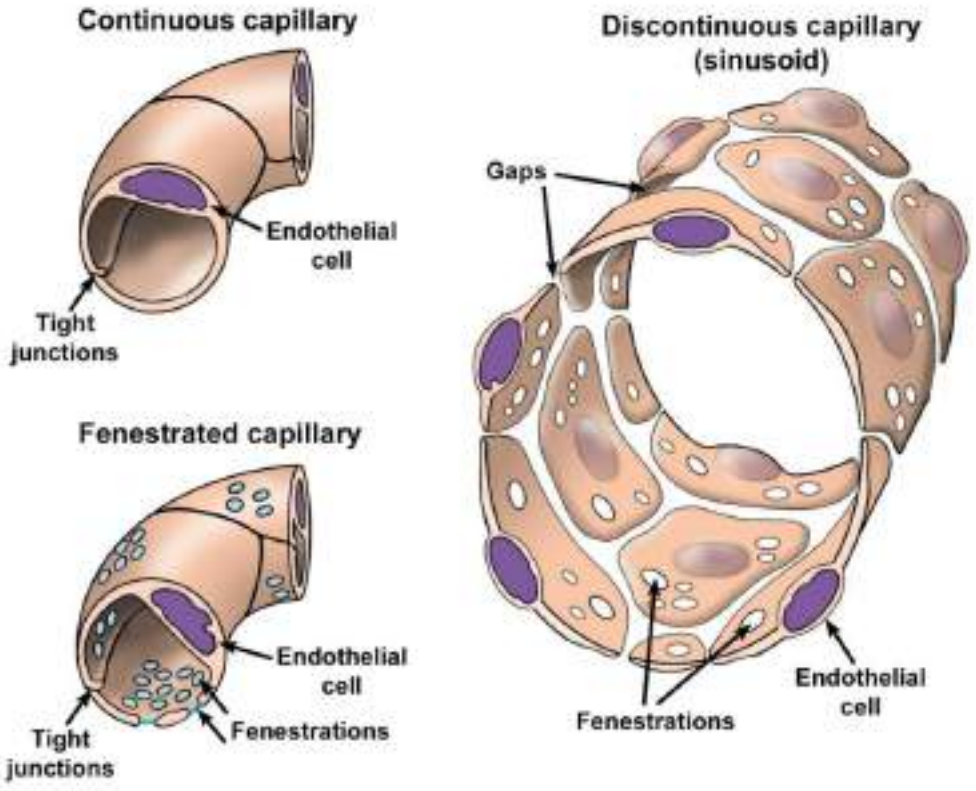

Figure 10.2. Types of capillaries

II. Types ***(images)***

A. **Continuous capillaries**

1. Most common

2. Endothelium is continuous (i.e., has no pores)

B. **Fenestrated capillaries**

1. Endothelium contains pores that may or may not be spanned by a **diaphragm**. If present, the diaphragm is thinner than two apposed

plasma membranes.

2. Pores with diaphragms are common in capillaries in the endocrine organs and portions of the digestive tract. Pores lacking diaphragms are uniquely present in the glomerular capillaries of the kidney.

3. Pores facilitate diffusion across the endothelium

C. **Discontinuous capillaries (sinusoids)**

1. Larger diameter and slower blood flow than in other capillaries

2. Endothelium has large pores that are not closed by a diaphragm.

3. Gaps are present between adjacent endothelial cells.

4. Partial or no basal lamina present.

5. Prominent in spleen and liver

VEINS *(images)*

I. General considerations

A. Return blood from capillary beds to the heart

B. Have thinner walls, larger lumens and more irregular cross-sectional outlines than arteries of similar size.

C. Tunica adventitia is the predominate tunic.

D. Larger veins possess **valves**, that are extensions of the tunica intima that serve to prevent back-flow of blood.

II. Types (Only features distinct to each type and different from the Basic Structural Organization are presented)

A. **Venules and small veins**

1. Tunica media is absent in venules. Smooth muscle fibers appear in the tunica media as venules progress to small veins.

2. **High endothelial venules***.* Venules in which the endothelium is simple cuboidal; facilitate movement of cells from the blood into the surrounding tissues (diapedesis). This type of venule is found in many of the lymphatic tissues.

B. **Medium veins**. Tunica media is composed of connective tissue and smooth muscle, with the latter increasing to form a more definitive and continuous portion as the vein increases in size. Most named veins are in this category.

C. **Large veins**, includes superior and inferior venae cavae; have well-developed, longitudinally oriented smooth muscle in the tunica adventitia in addition to the circularly arranged smooth muscle in the tunica media.

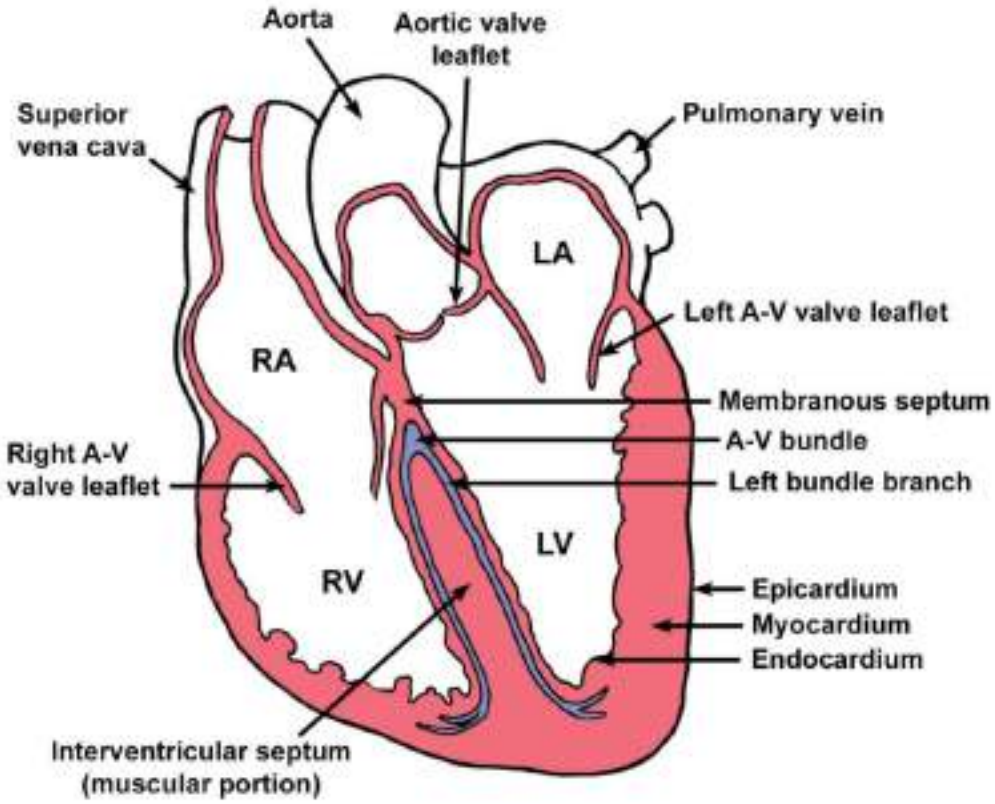

FIGURE 10.3. Diagram of a frontal section of the heart (RA, right atrium; LA, left atrium; RV, right ventricle; LV, left ventricle)

HEART *(images)*

I. Develops by a vessel folding back on itself to produce four chambers in the adult. Two upper chambers, **atria (singular, atrium)**, receive blood from the body and lungs; two **ventricles** pump blood out of the heart.

II. Tunics

A. **Endocardium**

1. Homologous to the tunica intima of vessels

2. Consists of an endothelium (simple squamous epithelium) plus underlying connective tissue of varying thickness. Smooth muscle may be present in the connective tissue layer.

3. **Cardiac valves**. Folds of the endocardium

    a. **Semilunar valves** at the bases of the aortic and pulmonary trunks prevent backflow of blood into the heart.

    b. **Atrioventricular valves (bicuspid and tricuspid)** prevent backflow of blood from the ventricles into the atria.

B. **Myocardium**

1. Composed of cardiac muscle

2. Fibers insert on components of the cardiac skeleton.

3. Thickest layer of the heart

4. Variation in thickness depends on the function of each chamber; thicker in ventricles than atria and thicker in left ventricle than right ventricle

C. **Epicardium (visceral pericardium)**

1. Serous membrane on the surface of the myocardium

2. Consists of a simple squamous epithelium and a loose connective tissue, with adipocytes, adjacent to the myocardium.

3. Coronary blood vessels are located in the connective tissue.

III. **Cardiac skeleton**. Thickened regions of dense connective tissue that provide support for heart valves and serve as insertion of cardiac muscle fibers

A. **Annuli fibrosi** are connective tissue rings that surround and stabilize each valve.

B. **Fibrous trigones** regions of connective tissue that connect the annuli fibrosis

C. **Membranous septum** is a connective tissue partition forming the upper portion of the interventricular septum; this connective tissue also separates the left ventricle from the right atrium.

IV. Impulse conducting system. Formed of specialized cardiac muscle fibers that initiate and coordinate the contraction of the heart

A. **Sinoatrial (SA) node** in the right atrium is the electrical **pacemaker** that initiates the impuse.

B. Fibers spread the impulse throughout the atria as well as transferring it to the atrioventricular node.

C. The **atrioventricular (AV) node** is located in the **interatrial septum**.

D. An **atrioventricular bundle** extends from the AV node in the **membranous septum** and bifurcates into right and left **bundle branches** that lie beneath the endocardium on both sides of the **interventricular septum**.

E. **Purkinje fibers**, modified, enlarged cardiac muscle fibers leave the bundle branches to innervate the myocardium.

CHAPTER 2

CELL STRUCTURE AND CELL DIVISION

GENERAL CONCEPTS

I. Heirarchy of body organization

   A. Cells

   B. Tissues (epithelium, muscle, connective, nervous)

   C. Organs (stomach, heart, skin, lung, etc.)

   D. Organ systems (digestive, respiratory, excretory, etc.)

   E. Individual

II. Although there are approximately 200 different cell types in the body, cells are more alike than different. Specialization of function, (e.g., glandular cells for secretion or muscle cells for contraction) is really an emphasis of a function that all cells possess to some degree. In some cases, cells have become so specialized that some functions are lost altogether (e.g., cell proliferation).

III. Cells are the structural units of all living organisms.

   A. Cells vary in size and shape according to location and function.

      1. Cells widely in diameter, from the largest, the mature human ovum (120 microns) to the smallest, the red blood cell (7-8 microns).

      2. Cells shapes. ***(images)***

         a. **Spherical**. Cells in a fluid environment, e.g., blood cells or some nerve cells

         b. **Squamous**. Flattened cells with a width much greater than height. Found at surfaces where rapid exchanges of gases or fluids occur.

         c. **Cuboidal**. Cells shaped like a cube, roughly equal height and width. Often form tubes or tubules.

         d. **Columnar**. Cells shaped like columns, much taller than they are wide. Often function in absorption.

e. **Pyramidal**. Cells shaped like a pyramid. Often found comprising spherical glandular structures.

f. **Stellate**. Star-shaped cells. Possess many slender processes for interaction with multiple cells such as neurons.

g. **Spindle-shaped**. Elongated shape with tapering ends.

B. Cells vary in internal structure depending upon their function.

1. Specialized cells possess abundant internal structures related to their specific function, e.g., contractile filaments in muscle cells or secretory granules in gland cells.

2. Cell polarity. Polarity is a feature of a cell which is exhibited when the organelles are not homogenously distributed in the cytoplasm. This distribution correlates with the function of the cell, e.g., secretion or absorption.

C. Cells vary in their life history, for example, rates of cell renewal.

IV. Major compartments of the cell

A. Cytoplasm. Composed of an aqueous matrix containing the internal structures of the cell, thus allowing for the cytosolic metabolic pathways (e.g., glycolysis) to function.

B. Nucleus

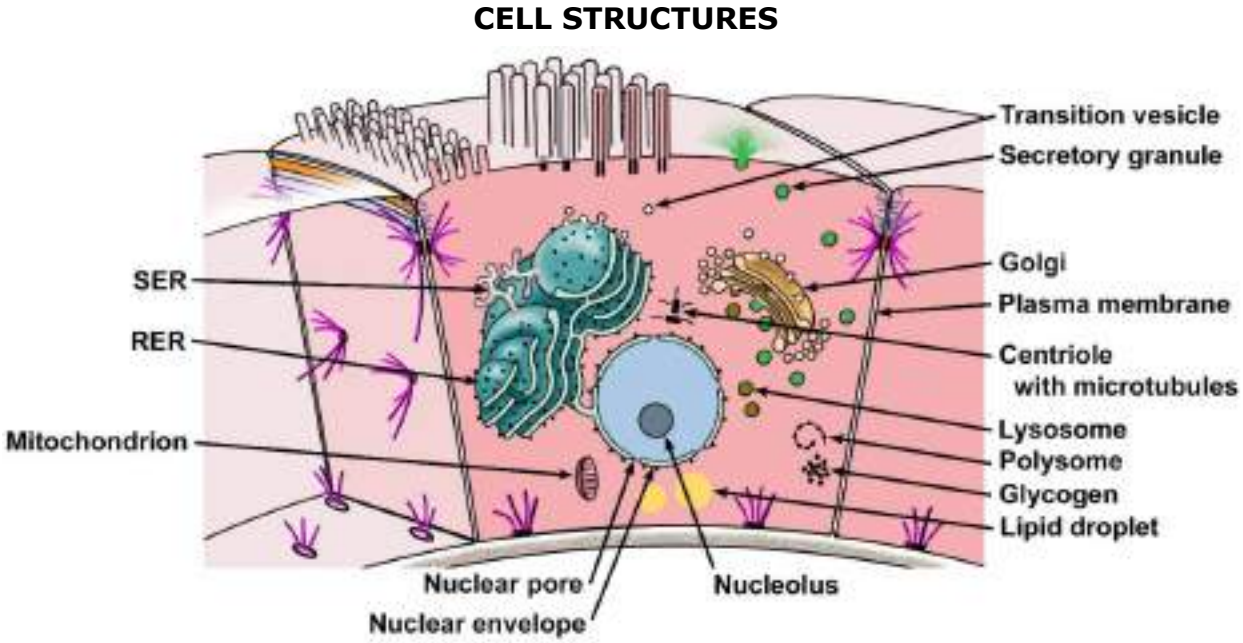

Figure 2.1. Structural features of a typical cell.

CELL MEMBRANES *(images)*

I. All membranes have a similar structure and are referred to as unit membranes. A specialized **unit membrane** forms the surface boundary of the cell and is called the **plasma membrane**. Other membranes are present within the cells, where they form mitochondria, endoplasmic reticulum, or nuclear envelope, for example. The structure of the unit membrane cannot be resolved with the light microscope; however, at high magnification with the electron microscope, it appears as a trilaminar dark-light-dark band.

   A. Fluid mosaic model of membrane structure

      1. **Phospholipid bilayer** consists of two leaflets of phospholipids.

         a. The polar, phosphate head groups face the surfaces of the membrane.

         b. The hydrocarbon tails form the hydrophobic core of the membrane.

      2. Membrane proteins

         a. **Integral membrane proteins** are proteins that extend into one or both of the phospholipid layers. Proteins that extend across both of the phospholipid layers are called transmembrane proteins.

         b. **Peripheral membrane proteins** are either associated with the polar head groups of the phospholipids or with integral membrane proteins. They do not contact the hydrophobic core of the membrane.

      3. **Glycocalyx** is composed of complex carbohydrates on the external surface of the plasma membrane. The carbohydrates are covalently attached to proteins or lipids.

II. Functions of the plasma membrane

   A. Membrane transport

      1. **Diffusion**

         a. Passive diffusion

         b. Facilitated diffusion. Utilizes transmembrane proteins to increase the permeability of the membrane to certain materials.

      2. **Active transport**. Energy-requiring process of moving materials across the membrane.

      3. **Vesicular transport**

a. **Endocytosis**. Internalization of small membrane vesicles formed from the plasma membrane

   i. **Pinocytosis** ("cell drinking"). Uptake of fluid into the cell by a continuous process

   ii. **Receptor-mediated endocytosis**. Requires receptor-ligand binding for vesicle formation and internalization

b. **Phagocytosis** ("cell eating"). Ingestion of large particles (e.g., bacteria) into the cell; prominent in some macrophages and white blood cells.

c. **Exocytosis**. Fusion of cytoplasmic vesicles with the plasma membrane and release of the vesicle contents to the outside of the cell

   i. **Constitutive exocytosis**. Continuous process that renews the plasma membrane.

   ii. **Regulated exocytosis**. Requires an extracellular signal for vesicle fusion and release (e.g., hormone secretion)

d. **Transcytosis**. Uptake of material on one side of a cell followed by transport and release from the opposite surface

B. Cell adhesion. Proteins provide cell-to-cell attachment and cell-to-extracellular matrix anchorage.

C. Intercellular communication. Transmembrane proteins assemble to form pores (gap junctions) between cells.

D. Signal transduction. Following interaction with extracellular signals, e.g., hormones and growth factors, receptor proteins initiate intracellular signaling pathways.

NUCLEUS *(images)*

I. Houses the DNA; produces ribosomes and messenger RNA

II. Components

A. **Nuclear envelope**

1. Composed of two unit membranes, **inner and outer nuclear membranes**, which are separated by the **perinuclear space**; outer

membranes and space are continuous with those of the endoplasmic reticulum.

2. Outer membrane possesses ribosomes.

3. **Nuclear pores**. Perforations in the nuclear envelope, provide direct, bidirectional continuity between the contents of the nucleus and the cytoplasm.

    a. Inner and outer nuclear membranes become continuous at the rim of the pore.

    b. Pores are surrounded by an octet of proteins with a central granule comprising the **nuclear pore complex**.

4. **Nuclear lamina**. Intermediate filaments on the inner nuclear membrane provide support for the nuclear envelope.

B. **Nucleolus**

1. Site of ribosomal RNA (rRNA) synthesis and initial ribosome subunit assembly

2. Subdivisions of the nucleolus

    a. **Nucleolar organizing centers (fibrillary centers)**. Pale staining regions containing DNA sequences that encode rRNA

    b. **Pars fibrosa (dense fibrillar components)**. Electron dense fibrillar regions composed of rRNA transcripts

    c. **Pars granulosa**. Granular-appearing regions composed of maturing ribosome particles

C. **Chromatin**

1. Composed of DNA plus protein, mostly histone protein

2. Chromatin exists in transcriptionally active and inactive states.

    a. **Euchromatin**. Refers to the state of chromatin that is transcriptionally active, dispersed, and pale staining

    b. **Heterochromatin**. Refers to the state of chromatin that is transcriptionally inactive, condensed, and dark staining

D. **Nucleoplasm**. Similar to cytoplasm, an aqueous matrix with cytoskeletal elements

ENDOPLASMIC RETICULUM *(images)*

I. Intracellular system of membranes

II. **Rough endoplasmic reticulum (RER)**

   A. Flattened membrane sacs; can occur singly or as multiple, parallel stacks

   B. Continuous with the nuclear envelope

   C. Possesses ribosomes on the cytoplasmic surface

   D. Site of protein synthesis and some phospholipid synthesis

III. **Smooth endoplasmic reticulum (SER)**

   A. Tubular membranous structures in a meshwork configuration that is continuous with rough endoplasmic reticulum; lack ribosomes

   B. Highly specialized in muscle cells where it is called the **sarcoplasmic reticulum**

   C. Functions

      1. Synthesis of triglycerides, cholesterol, and steroid hormones

      2. Detoxifies drugs

      3. Stores and mobilizes calcium

RIBOSOMES

I. **Ribsomes** are composed of two subunits containing rRNA and proteins.

II. Site of translation of messenger RNA (mRNA) to produce protein

III. Distribution

   A. Free in the cytoplasm. **Polysomes (polyribosomes)**, spiral clusters of ribosomes along a mRNA molecule; synthesize proteins for use in the cytoplasm, mitochondria, peroxisomes, and nucleus

   B. Associated with membranes

      1. Attached to the endoplasmic reticulum or outer nuclear membrane

CHAPTER 4

CONNECTIVE TISSUE PROPER

GENERAL CONCEPTS FOR ALL CONNECTIVE TISSUES

I. Connective tissues are unique in that they provide form and framework to organs and the body. The consistency of the framework they contribute varies from a liquid, to the pliancy of a gel, to the rigidity found in bone. Collectively, connective tissues are the only tissues that possess extensive extracellular components (stroma) in addition to parenchymal cells.

II. Functions

- A. Provides substance and form to the body and organs
- B. Defends against infection
- C. Aids in injury repair
- D. Provides a cushion between tissues and organs
- E. Stores lipids
- F. Provides a medium for diffusion of nutrients and wastes
- G. Attaches muscle to bone and bone to bone
- H. Provide support (cartilage and bone)

III. Components

- A. Cells
- B. Extracellular matrix
  1. Fibers
     - a. Collagen
     - b. Elastic
     - c. Reticular
- C. Ground substance

IV. Types of connective tissue. Classified by the relative abundance, variety and content of the components

A. Connective tissue proper

B. Cartilage (see Chapter 5)

C. Bone (see Chapter 5)

D. Special. Includes adipose, elastic reticular and mucus connective tissues as well as blood and hemopoietic tissue. (See Chapter 6)

COMPOSITION OF CONNECTIVE TISSUES

I. **Cells**. Each type of connective tissue has its own characteristic complement of one or more cell types. Cells specific to each type of connective tissue will be discussed with each tissue.

II. **Extracellular matrix** is synthesized and secreted by resident "blast" cells specific for each connective tissue type (e.g., fibroblasts and chondroblasts); Extracellular matrix is composed of:

A. **Fibers**. ***(images)***

Fiber type	Composition	Properties
Collagen	Collagen I, II	Inelastic, eosinophilic
Reticular	Collagen III	Inelastic, branched, argyrophilic
Elastic	Elastin	Elastic, eosinophilic

1. **Collagen fibers**

a. **Tropocollagen**

i. Collagen molecule subunit consisting of three alpha chains intertwined in a triple helix; collagen types are distinguished by their subunit composition.

ii. Produced by fibroblasts, chrondroblasts, chondrocytes and osteoblasts.

iii. Secreted into the matrix, where they orient themselves into fibrils with a 64 nm repeating banding pattern

b. Major collagen types

i. **Type I**. Fibrils aggregate into fibers and fiber bundles; most

widespread distribution; Forms a component of the extracellular matrix ("interstitial collagen"), tendons, ligaments and capsules of organs.

ii. **Type II**. Fibrils do not form fibers; present in hyaline and elastic cartilages

iii. **Type III**. Fibrils aggregate into fibers; present surrounding smooth muscle cells and nerve fibers. Forms the stroma of lymphatic tissues and organs.

iv. **Type IV**. Chemically unique form of collagen that does not form fibrils; major component of the basal lamina

2. **Elastic fibers**

a. Composed primarily of elastin

b. Elastin forms the central amorphous core of the fiber which is surrounded by microfibrils.

c. Unique chemical properties of elastin provide for elasticity.

d. Elastic fibers occur in nearly all connective tissues in varying amounts and are intermixed with collagen fibers. When present exclusively, they constitute elastic connective tissue.

e. Frequently difficult to differentiate from collagen with conventional stains.

3. **Reticular fibers**

a. Collagen type III fibers

b. Highly glycosylated and stain with silver (argyrophilic)

c. When they are the major fiber fiber type (e.g., in the stroma of lymphoid organs), they constitute reticular connective tissue.

B. **Ground substance**

1. An amorphous substance of variable consistencies from liquid to gelatinous (depending on connective tissue type), in which cells and fibers are embedded. Ground substance can also be impregnated with calcium phosphate to form a rigid solid in the case of bone. The differences in the ground substance among the connective tissues confer unique structural qualities to each connective tissue.

2. Functions

    a. Provides a medium for passage of molecules and cells migrating through the tissue.

    b. Contains adhesive proteins that regulate cell movements and provide anchorage.

    c. Retards passage of bacteria

    d. Provides a medium for passage of molecules and cells migrating through the tissue.

3. Components

    a. **Glycosaminoglycans (GAGs)**

        i. Long, unbranched polysaccharides composed of repeating disaccharide units, which are usually sulfated.

        ii. Large negative charge of the sugars attracts cations, resulting in a high degree of hydration. The matrix formed ranges from a liquid passageway to a viscous shock absorber.

        iii. GAGs are generally attached to proteins to form **proteoglycans**.

        iv. **Proteoglycan aggregate**. Many proteoglycans are attached to hyaluronic acid, which is itself a glycosaminoglycan.

    b. **Adhesive glycoproteins**. For example fibronectin and laminin.

    c. **Tissue fluid**. Contains salts, ions and soluble protein.

GENERAL CONCEPTS FOR CONNECTIVE TISSUE PROPER

I. Connective tissue proper comprises a functionally and structurally diverse group of tissues.

II. Functions

    A. Structural functions of connective tissue proper

        1. Forms a portion of the wall of hollow organs and vessels and the stroma of solid organs

        2. Forms the stroma of organs and subdivides organs into functional compartments

3. Provides padding between and around organs and other tissues

4. Provides anchorage and attachment (e.g., muscle insertions)

B. Provides a medium for nutrient and waste exchange

C. Stores lipid in adipocytes

D. Defends the body and provides immune surveillance via lymphoid and phagocytic cells

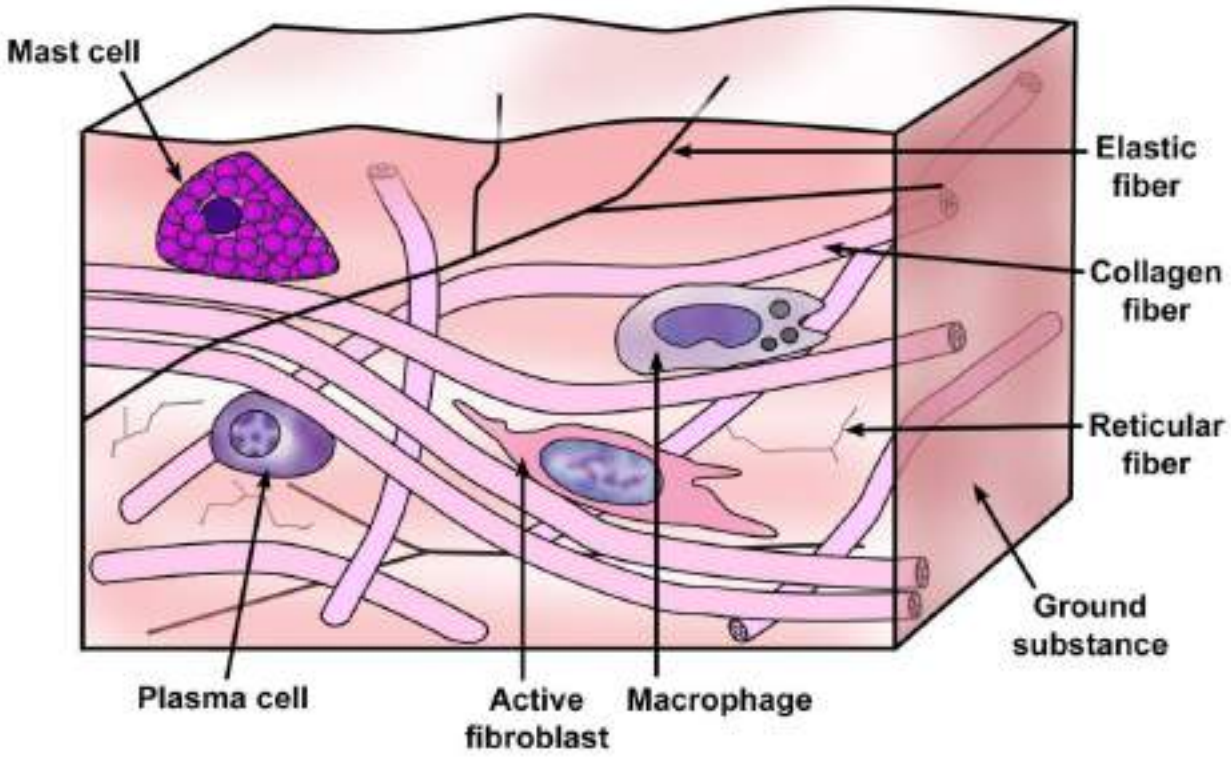

Figure 4.1. Components of connective tissue proper

CELLS OF CONNECTIVE TISSUE PROPER *(images)*

I. Connective tissue cells can be grouped into two major groups, resident and migratory.

A. **Resident cells** are present in tissues continuously and typically exhibit little movement. They can be regarded as permanent residents of the tissue. They can be derived from mesenchyme (embryonic connective tissue) and hemopoietic (bone marrow) tissue.

1. Fibroblasts

a. Synthesize and maintain fibers and ground substance

b. Major resident cell in connective tissue proper

c. Active and inactive fibroblasts

i. **Active fibroblast**

(a). Large, euchromatic, oval nucleus

(b). Cytoplasm not usually visible but contains abundant rough endoplasmic reticulum and Golgi

(c). Either elongated, spindle-shaped cells or stellate in shape, depending on connective tissue type in which they are located

(d). High synthetic activity

ii. **Inactive fibroblast**

(a). Small, heterochromatic, flattened nucleus

(b). Reduced cytoplasm and organelles

(c). Low synthetic activity

2. **Adipose cells (adipocytes, fat cells)**

a. Store lipids

i. Types

(a). **Yellow fat (unilocular)**

1. Each cell contains a single droplet of neutral fat (triglycerides) for energy storage and insulation.

2. Minimal cytoplasm, present as a rim around the lipid droplet

3. Flattened, heterochromatic, crescent-shaped nucleus that conforms to the contour of the lipid droplet

4. Can occur singly, in small clusters or forming a large mass, which is then referred to as adipose connective tissue

(b). **Brown fat (multilocular)**

1. Cells contain numerous, small lipid droplets.

2. Large numbers of mitochondria

3. Present mostly during early postnatal life in humans, abundant in hibernating animals for heat production

3. **Macrophages**

a. Derived from blood monocytes. Monocytes enter connective tissue from the bloodstream and rapidly transform into macrophages that function in phagocytosis, antigen processing, and cytokine secretion.

b. Comprise the mononuclear phagocyte system of the body that includes Kupffer cells in the liver, alveolar macrophages in the lung, microglia the central nervous system, Langerhan's cells in the skin, and osteoclasts in bone marrow.

c. Structure

i. Oval nucleus with an indentation in the nuclear envelope; prominent perinuclear heterochromatin

ii. Cytoplasm usually not visible unless it contains phagocytosed material

4. **Mast cells**

a. Mediate immediate hypersensitivity reaction and anaphylaxis by releasing immune modulators from cytoplasmic granules, in response to antigen binding with cell surface antibodies

b. Structure

i. Round to oval-shaped cells

ii. Round, usually centrally located nucleus

iii. Well-defined cytoplasm filled with secretory granules containing immune-modulatory compounds (e.g., histamine and heparin)

B. **Migratory cells**. Migratory or wandering cells are present only transiently and are mobile. They are white blood cells (WBC's leucocytes), derived from hemopoietic tissue in the bone and function primarily in connective tissue. Migratory cells, for the most part, are able to enter and leave the tissue in response to specific, local stimuli.

1. **Lymphocytes (T and B lymphocytes)**. Small spherical cells with sparse cytoplasm and a round heterochromatic nucleus, often with a small indentation

    a. **B cells**. Enter connective tissue and transform into plasma cells.

        i. Secrete antibodies to provide humoral immunity

        ii. Oval-shaped cells with a round, eccentrically located nucleus with heterochromatin clumps frequently arranged like the numerals on a clock face.

        iii. Basophilic cytoplasm due to large amounts of rough endoplasmic reticulum.

        iv. Well-developed Golgi complex appears as a distinct, unstained region in the cytoplasm near the nucleus and, for that reason, is often referred to as a **"negative Golgi"**.

    b. **T cells**. Provide cellular immunity and modulate the immune response. Primarily located in lymphatic tissues and organs; however can also be present in connective tissue proper.

2. **Neutrophils (polymorphonuclear leukocytes, PMNs)**

    a. Spherical cells with a heterochromatic nucleus with three to five lobes

    b. Pale-staining cytoplasmic granules

    c. Highly phagocytic cells that are attracted to sites of infection

3. **Eosinophils**

    a. Spherical cells with a bi-lobed nucleus

    b. Cytoplasmic granules stain intensely with eosin.

    c. Modulate the inflammatory process

CLASSIFICATION OF CONNECTIVE TISSUES *(images)*

I. Connective tissue proper

A. **Loose (areolar)**

1. Highly cellular, numerous cell types present

2. Fewer and smaller caliber collagen fibers compared with dense
3. Abundant ground substance, allows for diffusion of nutrients and wastes
4. Highly vascularized
5. Provides padding between and around organs and tissues

B. **Dense**

1. Fewer cells, mostly fibroblasts
2. Highly fibrous with larger caliber collagen fibers, provides strength
3. Minimal ground substance
4. Poorly vascularized
5. Types

a. **Dense, irregular connective tissue**. Fiber bundles arranged in an interlacing pattern; forms the capsule of organs and the dermis of the skin

b. **Dense regular connective tissue**. Parallel arrangement of fiber bundles; restricted to tendons and ligaments

II. Connective tissues with special properties

A. **Adipose connective tissue**. Consists of accumulations of adipocytes that are partitioned into lobules by septa of connective tissue proper. Provides energy storage and insulation

B. **Blood and hemopoietic (blood-forming) tissues** (Chapter 6)

C. **Elastic connective tissue**. Regularly arranged elastic fibers or sheets (e.g., the vocal ligament)

D. **Reticular connective tissue**. A loosely arranged connective tissue whose fibers are reticular fibers. Forms the stroma of hemopoietic tissue (e.g., bone marrow) and lymphoid organs (e.g., lymph node and spleen).

E. **Mucus connective tissue**. Embryonic connective tissue with abundant ground substance and delicate collagen fibers; present in the umbilical cord

III. **Supportive connective tissues – Cartilage and Bone** (Chapter 5)

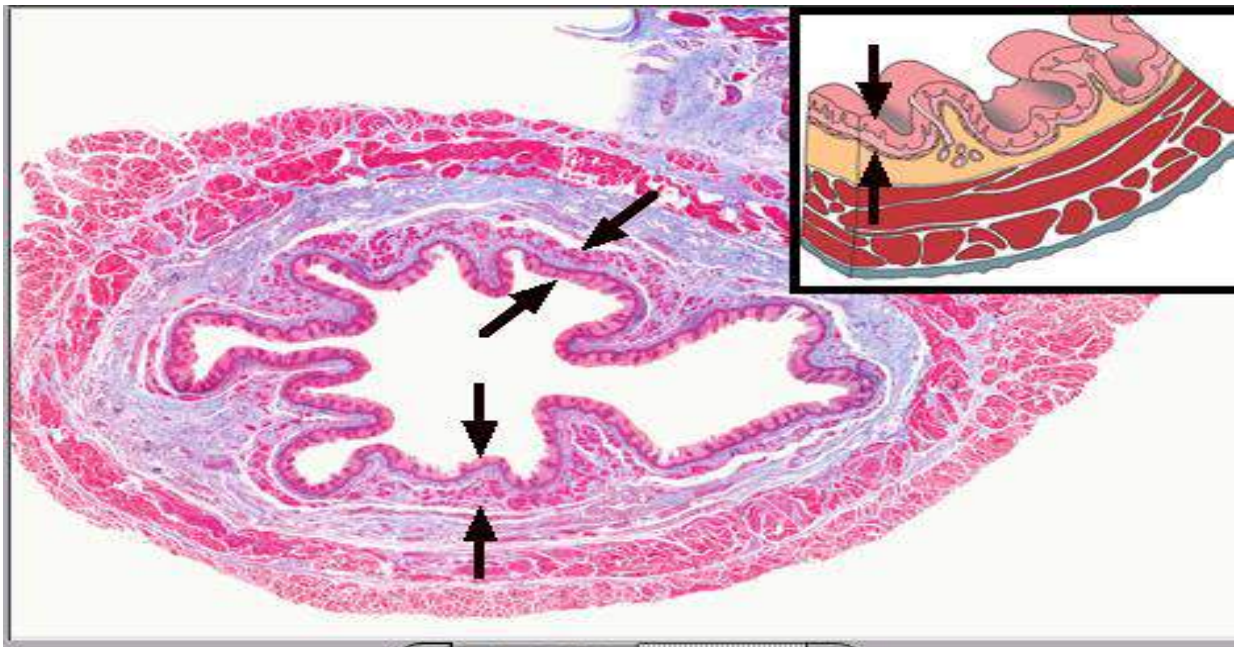
Esophagus: overview -- The esophagus is a muscular tube transporting partially digested food from the pharynx to the stomach. As are all organs opening to the exterior, the esophagus is composed of four tunics: mucosa; submucosa; muscularis externa; and adventitia (because the esophagus does not protrude into an internal body cavity). 10x.



1 of 10

The mucosa of the esophagus is lined with stratified squamous moist epithelium to protect the organ from the partially digested food. Mucous glands are located in the lamina propria in some regions, particularly near the gastro-esophageal junction and sometimes in the upper third.

1 of 6

Overview -- The four stomach regions comprise three functional units (cardia, body and fundus, pylorus), each composed of the expected four tunics. The stomach continues digestion by secreting pepsin to aid in protein digestion, by producing an acidic fluid, and by churning via the thick muscularis externa. Hormones secreted by enteroendocrine cells modulate digestion. 10x

Stomach: fundus and body -- The neck, the first part of fundic glands, contains mucous neck cells (darkly staining cells) and parietal cells. Mucous neck cells secrete a mucus different from that of the surface mucous cells. Parietal (oxyntic) cells, large, spherical and eosinophilic, are responsible for the HCl production in the stomach and also secrete gastric intrinsic factor. 200x, 100x

Although more numerous closer to the lumen of the stomach, parietal cells are also seen deep in the glands. They secrete HCl, which aids in digestion, converts pepsinogen into the active pepsin, and is bacteriostatic. Parietal cells resemble fried eggs, with abundant eosinophilic cytoplasm and a centrally located nucleus.

Chief cells secrete the enzyme precursor pepsinogen and, therefore, as protein-secreting exocrine cells, have basally located RER and apically located secretory granules. These cells are most numerous in the bases of the fundic glands, as seen here.

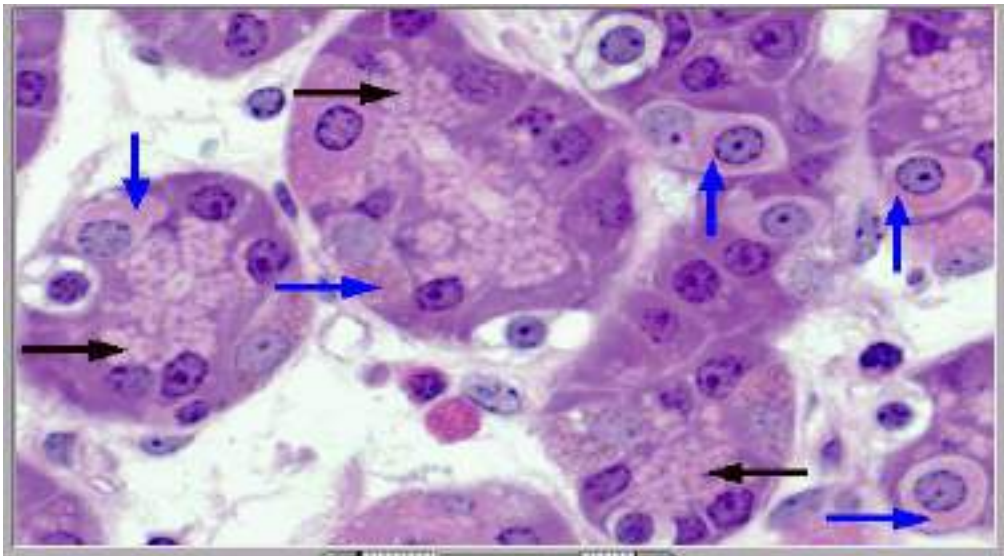
DNES (diffuse neuroendocrine system) cells are called enteroendocrine cells in the digestive system. They do not secrete their hormones into the lumens of the glands but into the surrounding connective tissue. Therefore, these cells are located at the periphery of the glands with their granules positioned away from the lumen and adjacent to the basement membrane.



8 of 13

Secretory granules of chief cells (black arrows) lie adjacent to the glandular lumens into which they are released (exocrine secretion). Conversely, the secretory granules (blue arrows) of enteroendocrine cells are located adjacent to the basement membrane of fundic glands because their secretory product is released into the lamina propria (endocrine or paracrine secretion).

Villi are finger-like projections from the surface of the small intestine into the lumen of the organ. Villi are composed of a central core of lamina propria covered by its overlying surface epithelium. The presence of villi are diagnostic for the small intestine.

1 of 9

Plicae circulares are circular folds extending around the inner circumference of the small intestine. The central core of each plica, formed by the submucosa, pushes up all the overlying layers. Therefore, the entire mucosa (including villi and glands) overlying the submucosal core is included in each plica.

Goblet cells are the second cell type in the epithelium. Mucin droplets produced by these cells accumulate in the bulging apex, while the nucleus and remaining cytoplasm form the "stem" of the each goblet. Goblet cells, found throughout the small and large intestines, produce mucus that lubricates the surface of the intestines.

CHAPTER 12

DIGESTIVE SYSTEM
(Oral cavity, tubular tract and glands)

LIP *(images)*

I. Forms the anterior boundary of the **vestibule**, the space between the inner surfaces of the lips and cheeks and the outer surface of the teeth and gums

II. Regions

A. Exterior surface

1. Covered by **thin skin**

2. **Hair follicles** and **sebaceous glands** are present

B. **Vermilion zone**

1. Forms the red-colored portion of the lip

a. Covered by a thin, stratified squamous keratinized epithelium

b. Mucosa contains numerous, densely packed dermal papillae

c. Papillae allow blood vessels close access to the surface

2. Lacks hair follicles

C. Inner surface

1. Lined by **oral mucosa**, stratified squamous moist epithelium

2. **Minor salivary glands (labial glands)** in the submucosa secrete both mucous and serous products.

III. **Orbicularis oris muscle**

A. Skeletal muscle arranged as a sphincter around the mouth.

B. Forms the core of the lip.

ORAL CAVITY

COMPONENTS

I. **Vestibule**. Bounded anteriorly and laterally by the lips and cheeks; bounded medially by teeth and gingiva (gums).

II. **Oral cavity proper**. Bounded anteriorly and laterally by the lingual surfaces of the teeth and gingiva, superiorly by the hard and soft palate, inferiorly by the tongue and floor of the mouth, and posteriorly by the pillars of the fauces leading to the pharynx

ORAL MUCOSA *(images)*

I. **Oral mucosa**, the mucous membrane (mucosa) lining the oral cavity and vestibule, is continuous with external skin and with the mucous membrane of the pharynx.

II. Composition

A. Epithelium. Stratified squamous keratinized or nonkeratinized depending on location

B. Lamina propria

C. Muscularis mucosae is not present.

D. Although not part of the oral mucosa, a submucosa of dense connective tissue, containing the minor salivary glands, underlies much of the oral mucosa.

III. Regional variations, depending on function and location

A. **Masticatory mucosa**

1. Located where mucosa is exposed to forces of mastication, such as gingiva and hard palate

2. Composition

a. Stratified squamous epithelium, keratinized

i. **Orthokeratinized epithelium** resembles the epidermis of the skin with a fully keratinized stratum corneum and is located in areas of maximal trauma.

ii. **Parakeratinized epithelium** does not fully keratinize, retaining

pyknotic nuclei and organelles in the surface cells. This epithelium is found in areas of reduced trauma.

b. Underlying submucosa is lacking in some locations.

B. **Lining mucosa**

1. Located where mucosa is not exposed to forces of mastication (minimal trauma), such as lining of lips and cheeks, soft palate, alveolar mucosa, undersurface of tongue, and floor of mouth

2. Epithelium. Stratified squamous epithelium, nonkeratinized (moist)

C. **Specialized mucosa**

1. Named "specialized" due to the presence of **taste buds**

2. Located on the dorsum of the tongue where it forms **papillae**

3. Epithelium

a. Stratified squamous keratinized, modified to form **filiform papillae** that facilitate the movement of food posteriorly

b. Stratified squamous moist, covering **fungiform** and **circumvallate papillae**

TONGUE ***(images)***

I. The subdivisions of the **tongue** are based on embryologic origins: anterior two two-thirds (body) and posterior one-third (root) are separated by the sulcus terminalis.

II. Composition

A. **Mucosa**. Dorsum of the tongue is covered by a specialized oral mucosa, modified to form papillae. (See "Specialized mucosa" above.) The ventral surface of the tongue is covered by a lining mucosa

B. The **submucosa** possesses **minor salivary glands** that are mucus-secreting except for those associated with the circumvallate papillae, which are serous-secreting

III. **Papillae**. Each consists of a connective tissue core covered by a stratified squamous epithelium.

A. **Filiform**

1. Most numerous; cover body of tongue

2. Cone-shaped protrusions angled so that they aid in movement of food toward the pharynx

B. **Fungiform**

1. Less numerous than filiform but also located on anterior two-thirds of tongue

2. Mushroom shaped, possess taste buds on superior surface

C. **Circumvallate**

1. Eight to twelve papillae located just anterior to the sulcus terminalis

2. Mushroom shaped and surrounded by a narrow moat; lateral wall of each papilla possesses taste buds

3. **Serous glands of von Ebner** open into the base of the moat and flush the moat for reception of new tastes.

D. **Foliate**. Parallel folds on the posterolateral surface of the tongue; not well developed in humans

IV. **Taste buds** are onion-shaped structures embedded in the surface of the fungiform and circumvallate papillae. Taste buds contain taste-receptor cells that communicate with the surface of the papilla through a **taste pore**. Depolarization of the taste cells leads to the stimulation of gustatory nerve fibers and the discrimination of sweet, salty, bitter, and sour sensations.

V. **Intrinsic tongue muscles**. Skeletal muscle bundles are arranged in three separate planes, with connective tissue bands from the lamina propria separating the bundles and firmly anchoring the muscle to the mucous membrane.

TEETH *(images)*

I. Overview of the **teeth**

A. **Anatomic crown**. The portion of the tooth covered by enamel.

B. **Anatomic root**. The portion of the tooth covered by cementum.

C. **Cervix**. Region where enamel abuts cementum

D. **Pulp cavity** is the central core of a tooth and is divided into a pulp chamber in the crown and a root canal in the root. An apical foramen at the tip of the root allows passage of nerves and blood vessels into and out of the pulp cavity.

E. **Gingiva**. Oral mucosa (masticatory) encircling the cervical region of the tooth and providing support for the tooth

II. Components

A. **Enamel** is the hardest tissue in the body, consisting of a mineralized tissue that is 96% hydroxyapatite. Enamel covers the anatomic crown of the tooth. During tooth development, enamel deposition by **ameloblasts** begins on the surface of dentin and progresses away from this **dentinoenamel junction**. No additional enamel can be formed after the tooth erupts, as the ameloblasts die on exposure to the oral cavity.

B. **Dentin**

1. Comprises the bulk of the tooth, underlying both enamel and cementum; dentin is a connective tissue that is 70% mineralized with hydroxyapatite.

2. Dentin is formed continuously throughout life by **odontoblasts** whose cell bodies line the pulp cavity.

3. Odontoblast processes extend through the dentin in S-shaped dentinal tubules radiating from the odontoblasts toward the **dentinoenamel** or **dentinocemental junctions**.

C. **Cementum**, a connective tissue mineralized with 50% hydroxyapatite, covers the anatomic root of the tooth. Cementum is formed continuously throughout life by activity of **cementoblasts** lying on the surface of the root at the interface of the cementum with the periodontal ligament.

D. The **pulp cavity** is lined by odontoblasts and filled with loose connective tissue, blood vessels, nerves, and lymphatics.

E. The **periodontal ligament**, collagen fiber bundles interconnecting cementum with the surrounding alveolar bone, suspends and supports each tooth in its alveolar socket.

MAJOR SALIVARY GLANDS *(images)*

I. Overview

A. All major salivary glands are compound, exocrine glands, and all open into the oral cavity.

B. Functions

1. Produce saliva to wet, lubricate, and buffer the oral cavity and its contents

2. Produce amylase for the initial digestion of carbohydrates

3. Produce lysozyme to control bacteria in the oral cavity

II. Major cell types

A. **Serous cells**

1. Synthesize, store, and release a thin, protein-rich secretion containing digestive enzymes, primarily amylase

2. Are pyramidal in shape and possess all organelles necessary for protein production and secretion (e.g., basal rough endoplasmic reticulum, Golgi, and apical secretory granules)

3. Are arranged into either:

a. **Acini** (singular, **acinus***)* or **alveoli** (singular, **alveolus***).* Flask-shaped sacs with tiny lumens

b. **Serous demilunes***.* Half moon–shaped caps positioned over the ends of mucous tubules

B. **Mucous cells**

1. Synthesize, store, and release mucus, a viscous, thick, glycoprotein secretion that protects and lubricates epithelia

2. Have flattened nuclei that are located at the bases of the cells along with the rough endoplasmic reticulum. Abundant **mucigen droplets** are located in the apex of each cell, giving it a frothy, vacuolated appearance.

3. Are organized in test tube–shaped **tubules** with relatively wide lumens

C. **Myoepithelial cells** are stellate-shaped epithelial cells with contractile functions that lie between the secretory or duct cells and the basement membrane. These cells contract to aid in movement of the secretory product.

III. Duct system conducts secretions to oral cavity.

A. Ducts are more numerous with serous acini than with mucous tubules because the tubules can act as their own ducts.

1. **Intralobular ducts**

    a. **Intercalated ducts** exit from secretory acini and are smaller in diameter than the acini they drain. These ducts are lined by simple cuboidal epithelia.

    b. **Striated ducts** continue from intercalated ducts and are larger in diameter than the secretory units they drain. They are lined by simple columnar epithelia. Numerous mitochondria and infoldings of the plasma membrane in the basal region of the cells give the duct a striated periphery. Striated ducts alter the content and concentration of the saliva.

2. **Interlobular ducts** form by the anastomosis of striated ducts and are located in the connective septa between lobules. Interlobular ducts are lined with simple columnar to stratified columnar epithelia.

3. The **main excretory duct(s)** is formed by the union of interlobular ducts. An excretory duct (s) is lined by a stratified epithelium that becomes stratified squamous moist just prior to its junction with the epithelium of the oral cavity.

IV. Major salivary glands

A. **Parotid glands**

1. Compound acinar glands producing only serous products; their secretions account for 25% of the saliva

2. Possess the most highly developed duct system of the major salivary glands

B. **Submandibular glands**

1. Compound tubulo-acinar glands producing both serous and mucous products, although serous acini predominate. Their secretions account for 70% of the saliva.

2. Serous cells are present as both acini and **serous demilunes**.

C. **Sublingual glands** secrete approximately 5% of the saliva. These are compound tubulo-acinar glands, producing both mucous and serous products, although mucous tubules predominate

TUBULAR DIGESTIVE SYSTEM

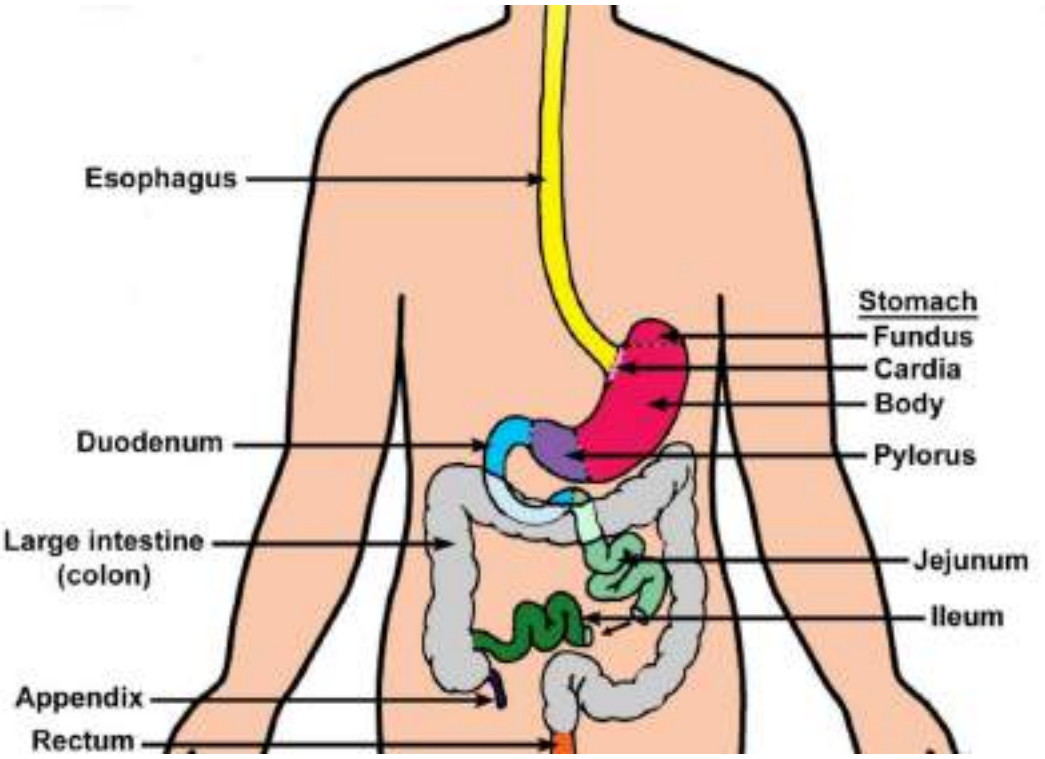

FIGURE 12.1. Organs comprising the tubular digestive tract.

COMPONENTS

I. Pharynx

II. Esophagus

III. Stomach

IV. Small intestine

V. Large intestine

VI. Anus

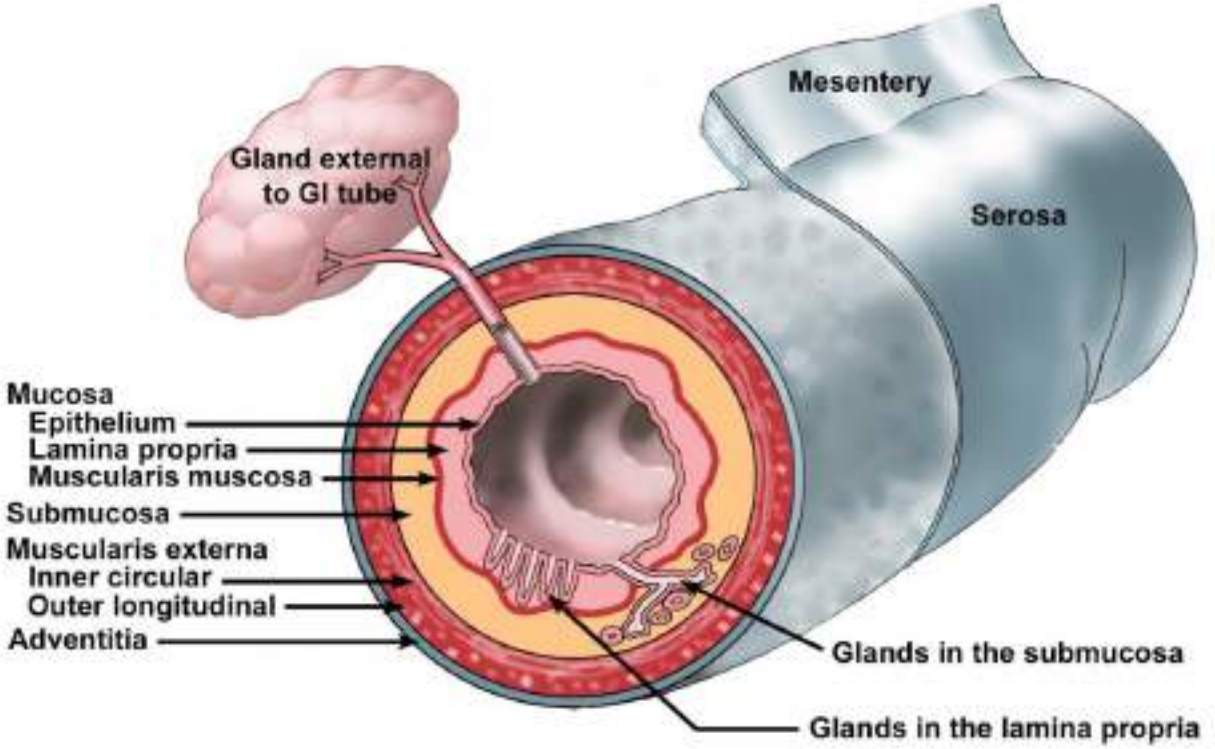

FIGURE 12.2. Overview of the layers and components of the tubular digestive tract.

BASIC HISTOLOGICAL ORGANIZATION

I. Layers

A. **Mucosa (mucous membrane)**. Innermost layer facing the lumen

1. **Epithelium**. Either a stratified squamous moist or a simple columnar epithelium

2. **Lamina propria**. Loose connective tissue; usually possesses digestive glands

3. **Muscularis mucosae** of smooth muscle is usually present.

B. **Submucosa**. Denser connective tissue than the lamina propria. The submucosa possesses **Meissner's nerve plexus** that supplies innervation to the muscularis mucosae and to digestive glands in the mucosa and submucosa. The submucosa possesses glands in the esophagus and duodenum.

C. **Muscularis externa** of smooth muscle is usually arranged into inner circular and outer longitudinal layers. **Auerbach's nerve plexus** is located between the two muscle layers and provides innervation to this smooth muscle.

D. **Serosa** (serous membrane) is present if the organ protrudes into the peritoneal cavity, or an **adventitia** (only the connective tissue portion of the serosa) is present if the organ is retroperitoneal.

II. Glands

A. Exocrine glands, aiding in digestion and/or lubrication, are located in:

1. Epithelium (e.g., goblet cells throughout the intestines)

2. Lamina propria (e.g., gastric glands)

3. Submucosa (e.g., Brunner's glands in the duodenum)

4. Glands located external to the digestive tract that open into the system (e.g., liver and pancreas)

B. Endocrine and paracrine cells, belonging to the diffuse **neuroendocrine system (DNES)**, are located throughout the mucosa of the gastrointestinal tract, influencing the secretion of glands and the motility of the gut.

VARIATIONS THAT DISTINGUISH EACH ORGAN FROM THE BASIC ORGANIZATIONAL PLAN

I. **Esophagus *(images)***

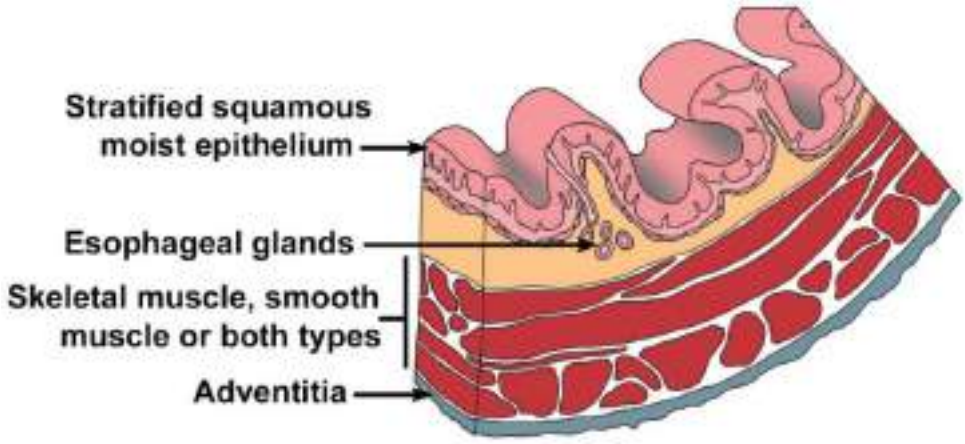

FIGURE 12.3. Cross-section of the esophagus.

A. Epithelium. **Stratified squamous nonkeratinized epithelium**

B. Lamina propria possesses **esophageal cardiac glands** that resemble the mucus-secreting glands of the cardiac portion of the stomach. These glands are particularly prominent near the junction of the esophagus with the stomach and are sometimes located in the beginning of the esophagus.

C. Submucosa has mucus-secreting, **esophageal glands proper**.

D. Muscularis externa is composed of **striated muscle** in the upper portion of the esophagus, skeletal, and smooth muscle in the middle portion, and smooth muscle in the lower portion.

E. Adventitia. Composed of loose connective tissue.

II. Stomach *(images)*

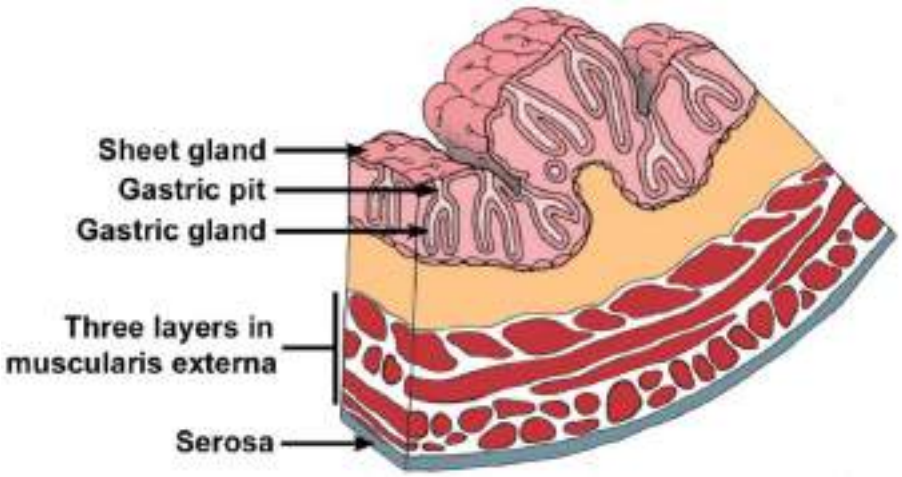

FIGURE 12.4. Cross-section of the stomach.

A. Structures present throughout the stomach

1. Surface epithelium

a. Simple columnar epithelium facing the lumen is modified so that all cells secrete mucus, forming a **sheet gland** that protects the stomach from its acidic environment.

b. **Gastric pit**. A channel formed by the invagination of the surface epithelium into the underlying lamina propria; connects the sheet gland with the gastric glands. The length of the gastric pit varies with each stomach region.

2. **Gastric glands**

a. Simple, branched tubular glands begin at a gastric pit and extend

through the lamina propria to the muscularis mucosae.

b. The region of the gland that attaches to the gastric pit is called the **neck region**; the base region of the gland is located adjacent to the muscularis mucosae.

c. Secretory cells in these glands vary in each region of the stomach.

3. Muscularis externa. Subdivisions of this smooth muscle layer frequently interdigitate, making it difficult to distinguish one layer from another.

a. Internal oblique layer

b. Middle circular layer that is modified in the pyloric region to form the pyloric sphincter

c. Outer longitudinal layer is separated from the inner circular layer by Auerbach's plexus, nerve fibers from the autonomic nervous system that supply

4. Serosa

5. **Rugae**. Longitudinal folds of the mucosa and submucosa in the undistended stomach allow for expansion.

B. Variations specific to the **cardiac region** (narrow region adjacent to the esophagus)

1. Abrupt transition of epithelium from stratified squamous moist of the esophagus to a sheet gland lining the cardiac stomach

2. Length of gastric pits is about equal to the length of cardiac glands

3. **Cardiac glands** primarily secrete mucus, although other products are also produced. Glands are frequently coiled.

4. Cardiac glands of the stomach extend into the lower esophagus, forming the esophageal cardiac glands.

C. Variations specific to the **fundic and body regions** (Glands in both regions are called fundic glands.)

1. **Fundic glands** are about twice as long as their gastric pits.

2. Cell types present in fundic glands:

a. **Stem cells** replenish both the surface epithelial cells and cells of the glands. Stem cells are located in the neck region.

b. **Mucous neck cells** are irregular in shape and stain basophilically. They secrete mucus and are located in the neck region.

c. **Parietal cells** are large, spherical, eosinophilic cells that secrete hydrogen and chloride ions and gastric intrinsic factor. They possess numerous mitochondria. An umbrella-shaped canaliculus indents the luminal surface, increasing surface area. Although present throughout the gland, parietal cells are more numerous in the upper regions.

d. **Chief or zymogen cells**, typical protein-producing cells, predominate in the bases; stain blue with hematoxylin and secrete pepsinogen.

e. **Enteroendocrine cells** (part of the diffuse neuroendocrine system, DNES) are located on the basement membrane and do not usually reach the lumen of the gland. This population of cells secretes a variety of hormones with endocrine and paracrine influences on digestive activity. Secretory granules cluster toward the basement membrane for their subsequent release into the lamina propria. Most common at the bases of the glands.

D. Variations specific to the **pyloric region**

1. Pits are longer in pylorus than in the cardiac region.

2. **Pyloric glands**, not as coiled as in the cardiac region; primarily secrete mucus.

3. Enteroendocrine cells are also present here.

4. Circular layer of muscularis externa is greatly thickened to form the **pyloric sphincter**.

III. Small intestine *(images)*

A. Subdivided into **duodenum**, **jejunum**, and **ileum**

B. Common features of the small intestine.

1. Structures that increase the surface area of the small intestine

a. **Microvilli**. Increase surface area of absorptive cells and, collectively, form a brush or striated border

b. **Villi**. Finger-like protrusions of the lamina propria and overlying epithelium into the lumen

i. Villi assume different shapes in each of the three intestinal subdivisions.

ii. A **lacteal** (blind-ending lymphatic capillary) is located in the center of each villus to absorb digested fat.

iii. Individual smooth muscle cells lie parallel to the long axis of each villus, "milking" the lacteal contents to the periphery.

c. **Plicae circulares**. Permanent circular folds formed by an up-welling of the submucosa and its overlying mucosa into the lumen. Villi protrude from the plicae.

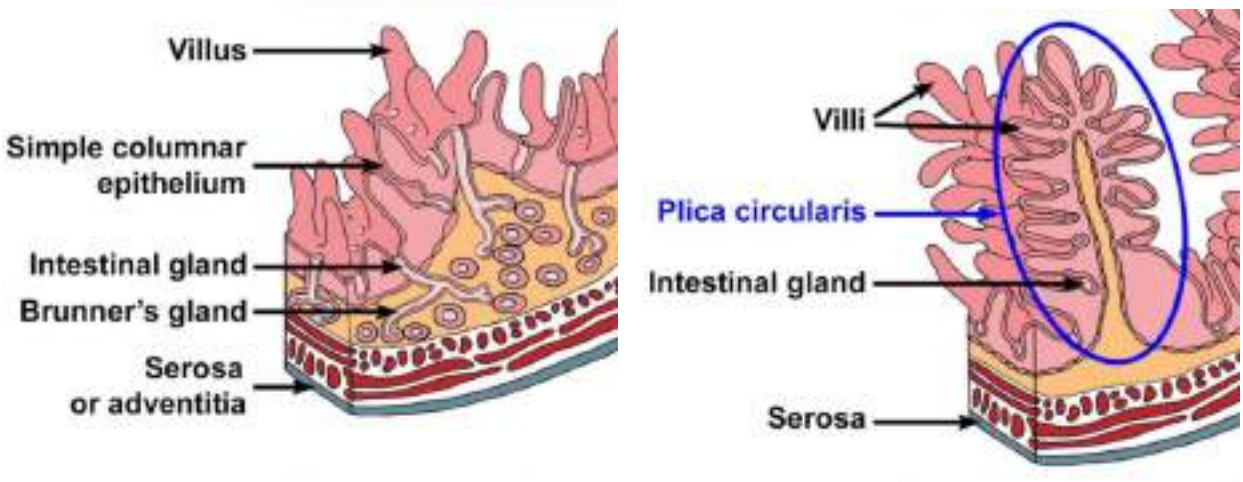

FIGURE 12.5. Longitudinal section through the duodenum (left) and the jejunum/ ileum (right). Note the orientation of the layers of muscularis externa when sectioned longitudinally.

2. Mucosal epithelium is composed of:

a. **Absorptive cells (enterocytes)**, forming a simple columnar epithelium with microvilli, absorb digested food

b. **Goblet cells** (unicellular glands) are interspersed among absorptive cells and secrete mucus. These cells increase in number from duodenum to rectum.

3. **Intestinal glands (crypts of Lieberkuhn)** are simple tubular glands that begin at the bases of the villi in the mucosa and extend through the lamina propria to the muscularis mucosae. Possess:

a. Absorptive cells

b. Goblet cells

c. **Paneth cells** possess large, eosinophilic granules whose contents, e.g, lysozyme, digest bacterial cell walls.

d. **Enteroendocrine cells**

4. Muscularis externa of inner circular and outer longitudinal layers with an intervening Auerbach's nerve plexus

5. Serosa covers all of small intestine except for the beginning of the duodenum, which is retroperitoneal and possesses an adventitia.

C. Variations specific to the intestinal subdivisions

1. **Brunner's glands** in the submucosa are present only in the duodenum. These compound tubular glands open into the bases of the intestinal glands and secrete an alkaline mucus to neutralize the acidity of the stomach contents.

2. **Peyer's patches** are clusters of 10-200 lymphoid nodules located primarily in the lamina propria of the ileum. Each cluster is positioned on the side of the intestine away from the mesentery and forms a bulge that may protrude into the lumen as well as into the submucosa.

IV. Large intestine (colon) *(images)*

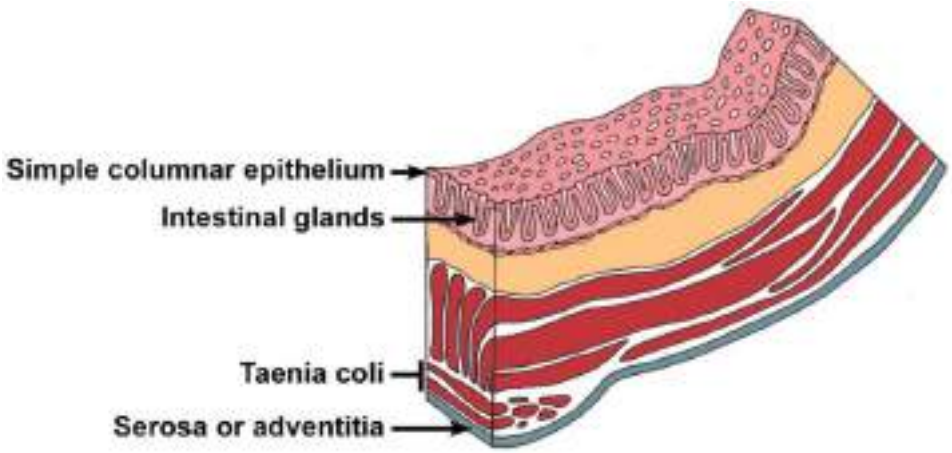

FIGURE 12.6. Cross-section of the large intestine.

A. Layers and structures forming the wall of the large intestine.

1. Mucosal epithelium:

a. Absorptive cells form a simple columnar epithelium with microvilli.

b. Goblet cells increase in number toward the rectum and provide lubrication.

c. A reduced number of enteroendocrine cells is present.

2. Intestinal glands (crypts of Lieberkuhn) are very straight in the large intestine.

3. No villi or plicae circulares are present in the large intestine.

4. Muscularis externa

a. Inner circular layer is complete around the circumference of the tube

b. Outer longitudinal layer is segregated into three longitudinal bands, the **taeniae coli**, that are placed equidistantly around the tube. The contraction of the taenia produces permanent sacculations in the large intestine, termed **haustrae**.

5. Either an adventitia or a serosa is present, depending on the particular portion of the large intestine.

B. The **appendix** resembles the large intestine except that the outer longitudinal smooth muscle layer is complete. Additionally, abundant lymphoid tissue is present in the lamina propria to protect against invading microorganisms.

C. Regions

1. **Ascending colon**. Rises on the right side of the abdominal cavity.

2. **Transverse colon**. Horizontal region that passes across the abdomen from right to left below the stomach.

3. **Descending colon**. Descends on the left side of the abdominal cavity.

4. **Sigmoid colon**. "S"-shaped

5. **Rectum** is a 12-cm-long tube continuing from the sigmoid colon. The mucosa of the rectum is similar to that of the majority of the large intestine. The rectum narrows abruptly to become the anal canal.

D. **Anal canal**. The terminal portion of the intestinal tract is about 4 cm long.

1. The intestinal glands disappear and the epithelium undergoes an abrupt transition from simple columnar to stratified squamous with sebaceous and apocrine sweat glands.

2. The inner circular portion of the muscularis externa expands to form the internal anal sphincter. The external anal sphincter is composed of skeletal muscle.

V. The **anus** is located at the level of the external anal sphincter and is covered by stratified squamous keratinized epithelium (skin).

MAJOR DIGESTIVE GLANDS

PANCREAS *(images)*

OVERVIEW

I. Located in the abdomen in the curve of the duodenum and divided into a **head**, **body**, and **tail**

II. Is both an exocrine and an endocrine gland

A. The exocrine portion produces an alkaline secretion containing digestive enzymes that empties into the duodenum.

B. The endocrine portion secretes insulin, glucagon, and somatostatin that regulate blood glucose levels.

STRUCTURE

I. **Exocrine pancreas**

A. Compound acinar gland; the acinar cells secrete numerous digestive enzymes that break down proteins, carbohydrates, lipids, and nucleic acids.

B. Cells show polarity with basal rough endoplasmic reticulum and apical secretory granules.

C. Duct system

1. Ducts begin as **centroacinar cells** located within the acini.

2. Intercalated ducts are lined with simple cuboidal epithelium. Centroacinar cells and cells of the intercalated ducts secrete bicarbonates to neutralize the acidity of the stomach contents (chyme) entering the duodenum.

3. Striated ducts are not present.

4. Interlobular ducts lead into one or more excretory ducts that empty into the duodenum.

D. Resembles the parotid gland except the pancreas has centroacinar cells and fewer ducts.

E. Secretion is regulated by cholecystokinin and secretin from enteroendocrine cells in the small intestine

II. **Endocrine pancreas (islets of Langerhans)**

A. Small clusters of cells, richly supplied by fenestrated capillaries, are scattered throughout the exocrine pancreas; these clusters show no orderly arrangement of secretory cells within the cluster.

B. Predominate cell types and secretions

1. **A cell (alpha cell)**. Secretes glucagon, which elevates glucose levels in the blood

2. **B cell (beta cell)**. Secretes insulin, which lowers blood glucose levels; predominant cell type

3. **D cell (delta cell)**. Secretes somatostatin, which modulates release of the other two major hormones

C. Individual cell types cannot be distinguished with routine hematoxylin and eosin staining.

LIVER *(images)*

OVERVIEW

I. Located in right, upper quadrant of abdominal cavity under the diaphragm

II. Both an exocrine and an endocrine gland

A. Exocrine secretion (bile) is stored in the gall bladder and released into the duodenum. This secretory product contains bile acids that aid in the emulsification of lipids, bilirubin (the breakdown product of hemoglobin), phospholipids, and cholesterol.

B. Endocrine function is the synthesis of plasma proteins, including albumin, clotting factors, and lipoproteins that are released into the liver sinusoids.

III. Additional functions include the metabolization of digested food, storage of

glucose as glycogen, and detoxification of hormones and drugs.

CYTOARCHITECTURE OF THE CLASSIC LIVER LOBULE

I. The classic **liver lobule** resembles a column similar to a stack of covered-wagon wheels.

II. Spokes of the wheels are cords or plates of **hepatocytes** radiating out from a central axis.

III. Spaces between the spokes are occupied by **liver sinusoids** (discontinuous sinusoidal capillaries).

IV. Central axis of the lobule is a **central vein** into which sinusoids drain (i.e., blood is flowing from the periphery of the lobule to the center). The central vein runs parallel to the long axis of the lobule.

V. The perimeter of the lobule (the wheel rim) is difficult to distinguish in the human. The perimeter is denoted by the position of three to six **portal canals (hepatic portal triads)** situated at intervals around the lobule.

   A. Portal canals run parallel to the long axis of the lobule.

   B. Portal canals contain branches of the

      1. **Hepatic portal vein**. Lined with simple squamous epithelium; has the largest diameter of the three structures

      2. **Hepatic artery**. Lined with simple squamous epithelium and two-three layers of smooth muscle

      3. **Bile duct**. Lined with simple cuboidal epithelium; multiple branches may be present

BLOOD SUPPLY AND DRAINAGE OF THE LIVER

I. Blood supply is from two sources

   A. **Hepatic portal vein**

      1. Supplies about 75% of the blood

      2. Carries blood drained directly from the gastrointestinal tract, which, therefore, is deoxygenated and high in absorbed nutrients.

   B. **Hepatic artery**. Supplies oxygenated blood

II. Branches from both vascular sources continue into smaller branches located in the portal canals. Portal canal branches supply the hepatic sinusoids that drain into a central vein. Multiple central veins anastomose to eventually form the three hepatic veins that empty into the inferior vena cava.

FUNCTIONAL MICROANATOMY

I. Sinusoids

A. A variation of discontinuous capillaries, in that gaps exist between endothelial cells and the fenestrations lack diaphragms

B. The basal lamina is lacking beneath the fenestrations.

C. Fenestrations open into a subsinusoidal space, the **space of Disse**, separating the sinusoids from the hepatocytes beneath the space.

D. **Kupffer cells**, liver macrophages, span the sinusoids, filtering debris from the blood.

II. Hepatocytes (liver cells)

A. Arranged as walls one to two cells thick that radiate out from the central vein like the spokes of a wheel

B. Histology

1. Cells are polyhedral in shape.

2. Cells possess one or two nuclei.

3. Cells contain abundant smooth and rough endoplasmic reticulum, Golgi apparatus, mitochondria, and lysosomes. They also contain large accumulations of electron-dense glycogen granules that stain strongly with PAS. Numerous peroxisomes, along with smooth endoplasmic reticulum, carry out detoxification.

4. At intervals between adjacent cells, the plasma membranes bulge inward to form a bile canaliculus, the beginning of the bile transport system.

5. Microvilli project into the space of Disse, increasing surface area of the cells.

FLOW OF BILE FROM LIVER

I. Bile is produced by hepatocytes in the liver and released into **bile canaliculi** located between two adjacent hepatocytes.

II. Bile canaliculi form a meshwork configuration that continues into bile ducts lying in portal canals. These **bile ducts** anastomose to form the left and right **hepatic duct**.

III. The hepatic ducts exit from the liver and fuse to form the **common bile duct**. The bile it contains can either:

   A. Travel directly to the duodenum

   B. Be transported via the **cystic duct** to the gall bladder where it is stored until needed

GALL BLADDER *(images)*

OVERVIEW

I. Stores and concentrates bile produced in the liver

II. Connects, via the **cystic duct**, with the hepatic duct from the liver to form the common bile duct that empties into the duodenum

MICROANATOMY

I. Mucosa

   A. Composed of:

      1. Simple columnar epithelium with short microvilli. Accumulations of mitochondria and glycoprotein-filled secretory vesicles, particularly in the apices of the cells, are prominent.

      2. Lamina propria

      3. Muscularis mucosae is not present.

   B. Is thrown into complex, irregular folds that are particularly evident when the gall bladder is empty.

II. Submucosa

III. Smooth muscle is arranged in an irregular network surrounding the gall bladder.

IV. A serosa covers most of the gall bladder; an adventitia surrounds the portion that is attached to the liver.

CHAPTER 20

EAR

COMPONENTS *(images)*

I. **External ear**. Receives sound waves, transmitting them to the tympanic membrane

II. **Middle ear**. Transmits movement of the tympanic membrane by three ear ossicles to fluid in the inner ear

III. **Inner ear**. Contains a receptor that responds to these fluid vibrations for the perception of sound. Additional receptors in the inner ear respond to the effects of gravity and motion of the head to maintain equilibrium.

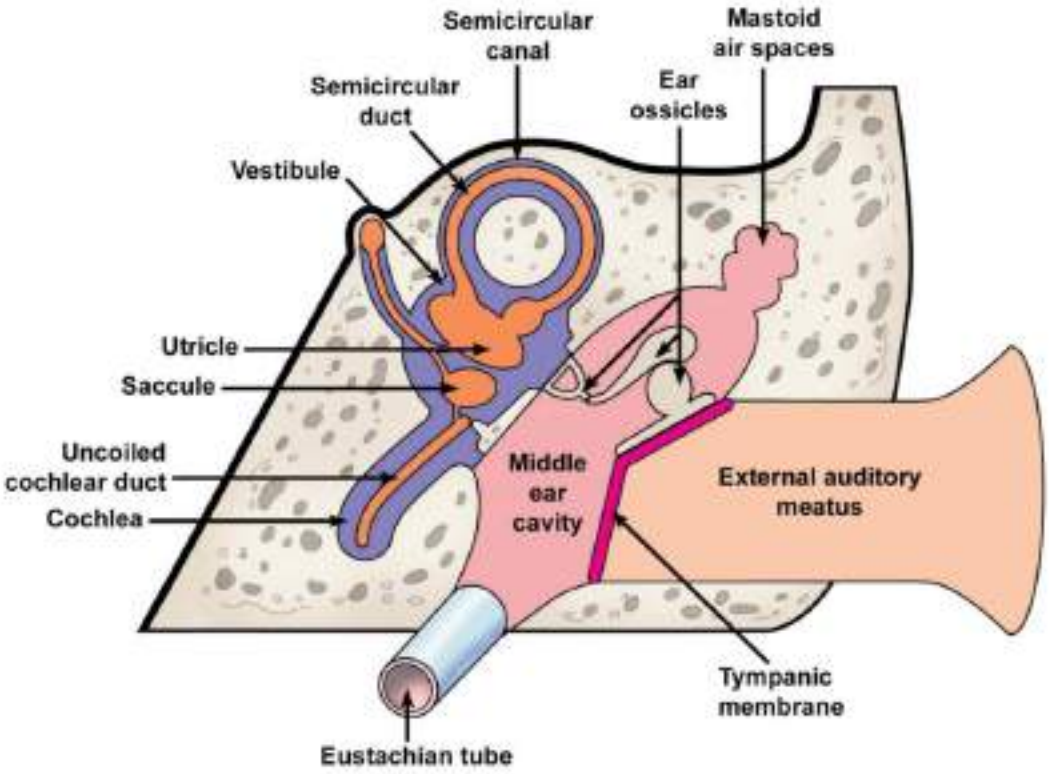

FIGURE 20.1. Schematic illustration of the three subdivisions of the ear embedded in the temporal bone.

EXTERNAL EAR *(images)*

I. **Auricle** or **pinna**. Shallow appendage on the lateral surfaces of the head that is

formed by thin skin covering a framework of elastic cartilage

II. **External auditory meatus**. Short tube leading to the tympanic membrane

A. The thin skin, lining the meatus, possesses ceruminous glands. Their secretions combine with those of adjacent sebaceous glands to form cerumen, a thick, waxy product.

B. Support provided by:

1. Elastic cartilage in the outer portion

2. Temporal bone in the inner portion

III. **Tympanic membrane** (ear drum) separates external from the middle ear.

A. Composition (from exterior to interior). Thin skin, two layers of collagen and elastic fibers with radial then circular arrangements, and a mucous membrane that is continuous with that lining the middle ear

B. Attachment of the malleus, an ear ossicle, to the inner surface pulls the tympanic membrane into a flattened, cone shape.

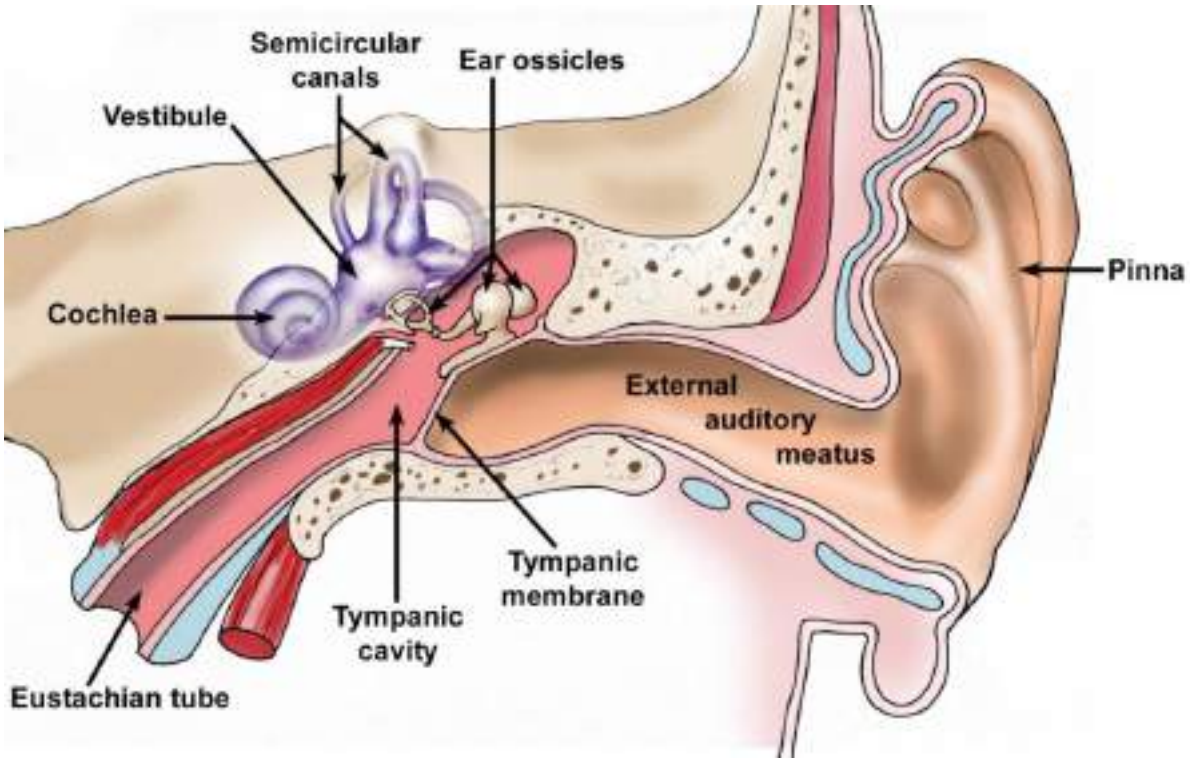

FIGURE 20.2. Coronal section through the skull showing the three subdivisions of the ear in the temporal bone.

MIDDLE EAR (TYMPANIC CAVITY) ***(images)***

I. The **middle ear** or **tympanic cavity** is a cavity within the temporal bone that is bounded by the tympanic membrane laterally and the bony wall of the inner ear medially. It communicates with the mastoid air cells posteriorly, and with the nasopharynx, via the Eustachian tube, anteriorly.

II. Structure

A. Lined by a mucous membrane whose epithelium is predominately simple squamous

B. Ear ossicles, small bones, transmit vibrations from the tympanic membrane to the inner ear.

1. Components

a. **Malleus**. Attached to the tympanic membrane

b. **Incus**. Interconnects malleus with stapes

c. **Stapes**. Footplate of the stapes fits into the oval window of the inner ear

2. Ossicles are connected to each other by ligaments and are covered with mucosa.

3. Small muscles attached to malleus (**tensor tympani**) and stapes (**stapedius**) modulate vibrations of these ossicles.

C. **Eustachian tube** (auditory tube)

1. Connects middle ear with the nasopharynx

2. Is lined by a mucous membrane whose epithelium becomes pseudostratified near the nasopharynx. Cilia associated with this epithelium beat toward the pharynx.

3. Is supported first by bone and then by cartilage and fibrous tissue as it nears the nasopharynx

4. Is usually collapsed but opens during swallowing to equilibrate air pressure

D. **Oval window** and **round window**

1. Openings in the petrous portion of the temporal bone that forms the medial wall of the middle ear

2. The oval window is occupied by the footplate of the stapes.

3. The round window is covered by a membrane that bulges to relieve pressure in the cochlea that originates from motion of the stapes at the oval window.

E. **Mastoid air spaces**, located in the mastoid process of the temporal bone, communicate posteriorly with the middle ear.

INNER EAR *(images)*

I. The **inner ear** is located in the **petrous portion of the temporal bone**.

II. Components

A. **Osseous labyrinth**. Series of interconnected tubular and cavernous spaces in the petrous portion of the temporal bone that are lined with periosteum and filled with perilymph fluid

1. **Vestibule**. Centrally located chamber; communicates with middle ear via the oval window

2. **Semicircular canals**

a. Are three tubular spaces that communicate with and lie posterolaterally to the vestibule

b. Are oriented in three mutually perpendicular planes

c. An enlargement at one end of each canal, adjacent to the vestibule, houses the ampulla of the semicircular ducts.

3. **Cochlea**. An osseous tube that connects with and lies anteromedially to the vestibule

a. Tube is coiled into a spiral shape with 2.5 turns, resembling a snail shell.

b. The tube's spiraling in the temporal bone results in the formation of a central, bony axis for the cochlea called the **modiolus**, which resembles a screw. The threads of the screw project into the cochlea and are called the **osseous spiral lamina**.

c. The modiolus houses the cochlear division of **cranial nerve VIII** and its sensory ganglion, the **spiral ganglion**.

B. **Membranous labyrinth**. Series of interconnected ducts and chambers that are suspended within the osseous labyrinth. Contain the fluid, endolymph. These ducts and chambers contain receptors for hearing and for static and kinetic senses.

1. **Utricle** and **saccule**. Suspended within the vestibule. A receptor, the **macula**, in each of these two chambers responds to stimuli of linear acceleration and gravitational forces.

2. **Semicircular ducts** (three). One duct is suspended in each of the semicircular canals; both ends of each duct connect with the utricle. An enlargement, the **ampulla**, at one end of each duct is located in the enlargement of each semicircular canal and contains a receptor, the **crista ampullaris**, for angular acceleration.

3. **Cochlear duct**. Located in the center of the cochlea. The cochlear duct communicates indirectly with the saccule. The receptor in the cochlear duct, the **organ of Corti**, responds to sound vibrations.

4. **Endolymphatic duct**. Formed by union of small ducts from the utricle and saccule; extends toward the brain where it terminates as an enlargement, the endolymphatic sac, between layers of the meninges. Probably functions to absorb **endolymph**.

C. Sensory innervation is provided by **cranial nerve VIII, the vestibulocochlear nerve**.

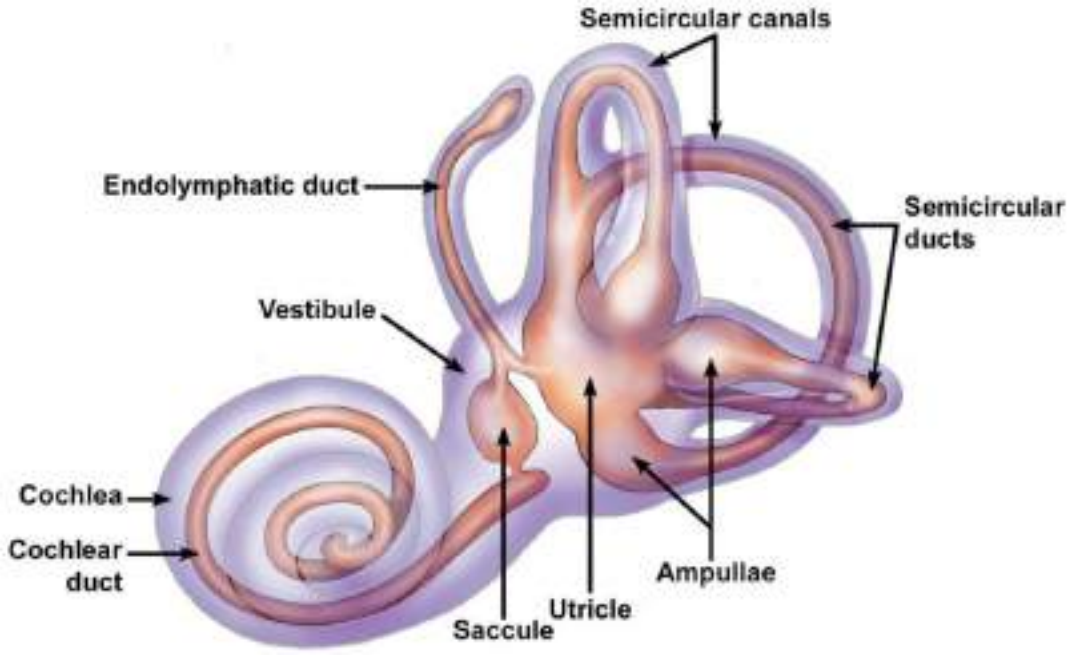

FIGURE 20.3. Inner ear: the membranous labyrinth is suspended in the osseous labyrinth.

III. **Utricle** and **saccule**

A. Portions of the membranous labyrinth that are connected to each other and are suspended in the osseous vestibule

B. **Macula**. Receptor in both the utricle and saccule

1. Thickening in the wall of the utricle and saccule composed of:

a. **Supporting cells**

b. **Hair cells** with stereocilia and a cilium (**kinocilium**) that are embedded in the gelatinous layer

c. **Gelatinous layer** is produced by supporting cells and covers both these and the hair cells.

d. **Otoliths** (**otoconia**). Calcium carbonate crystals that are suspended at the top of the gel

2. Linear acceleration and the force of gravity displace the otoliths, stimulating the stereocilia and kinocilia and initiating a neural, sensory impulse in the vestibular division of cranial nerve VIII.

IV. **Semicircular ducts** (three)

A. Portions of the membranous labyrinth suspended in the osseous semicircular canals; both ends of each semicircular duct connect to the utricle.

B. **Crista ampullaris**. Receptor in the ampullary enlargement of each semicircular duct

1. Ridge-like structure that lies perpendicular to the long axis of each duct. Internal cell structure is similar to that of a macula except:

a. Gelatinous layer, called the **cupula**, is shaped like a cone and extends across the ampulla to the opposite wall, thus spanning the duct.

b. Otoliths are absent.

2. Angular acceleration displaces the cupula that deflects the stereocilia and kinocilia and initiates a neural, sensory impulse in the vestibular division of cranial nerve VIII.

3. Orientation in three distinct planes allows for complex detection of motion.

V. Cochlear duct

A. Wedge-shaped duct of the membranous labyrinth suspended in the middle of the tubular, osseous cochlea. Position of the cochlear duct separates the bony cochlea into three subdivisions.

1. **Scala vestibuli**. This subdivision of the cochlea is continuous with the vestibule and lies above the cochlear duct, separated from it by the vestibular membrane.

2. **Cochlear duct**. Contains the receptor for sound. The cochlear duct is located in the middle of the cochlea and is continuous with the saccule through a small duct. Its roof is the vestibular membrane separating it from the osseous scala vestibuli. Its floor is formed by the basilar membrane that is continuous with the osseous spiral lamina; both separate the cochlear duct from the scala tympani.

3. **Scala tympani**. Subdivision of the bony cochlea lying beneath the cochlear duct. The scala tympani is continuous with the scala vestibuli at the **helicotrema**, located at the tip of the cochlea. The scala tympani terminates at the round window where pressure on the perilymph in this scala, initiated at the oval window and transported through scala vestibuli to scala tympani, is released.

B. **Organ of Corti**. Receptor for sound in the cochlear duct; positioned on the floor of the cochlear duct, resting on the basilar membrane

1. Structure

a. **Supporting cells**. Several varieties, including pillar cells that form the boundary of a triangular space called the inner tunnel. Provide support for the hair cells, among other functions.

b. Inner and **outer hair cells**. Receptor cells located on either side of the inner tunnel possess stereocilia that are embedded in the tectorial membrane.

c. **Tectorial membrane**. This gelatinous membrane extends over the hair cells and is secreted by the cells of the spiral limbus, resting on the osseous spiral lamina. Stereocilia of the hair cells are embedded in the tectorial membrane.

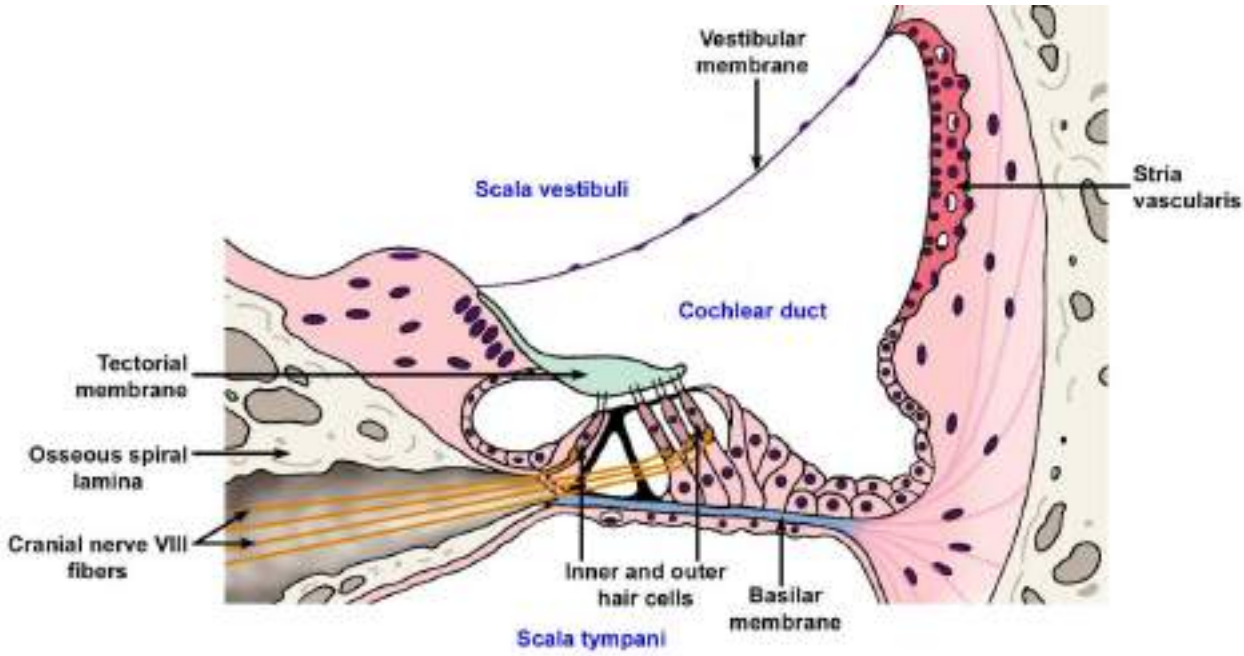

FIGURE 20.4. Cochlear duct, the receptor for sound, is a part of the membranous labyrinth in the inner ear.

2. Functions to discriminate sound

    a. Inward movement of the stapes at the oval window generates pressure on the perilymph in the vestibule that is transmitted into the scala vestibuli.

    b. From the scala vestibuli, pressure is conducted, by deflection of the vestibular membrane, to the endolymph of the cochlear duct and to the basilar membrane. Movement of the basilar membrane into scala tympani and away from the tectorial membrane causes a shearing force on the stereocilia embedded in this membrane and initiates a neural, sensory response in the cochlear division of cranial nerve VIII.

    c. Sound vibrations in the scala vestibuli also continue into the scala tympani at their junction at the **helicotrema**.

    d. Sound vibrations in scala tympani are relieved by the bulging of the round window into the middle ear.

3. **Stria vascularis** is a vascularized epithelium located on the outer wall of the cochlear duct that produces endolymph.

CHAPTER 16

ENDOCRINE SYSTEM

GENERAL CONCEPTS

I. Endocrine cells release their secretory products, called hormones, into the surrounding extracellular space. Hormones can affect adjacent cells (**paracrine secretion**) or diffuse into capillaries to be transported in the blood (**endocrine secretion**). Although exposed to all cells, Hormones act only on selected cells, called **target cells**, which express specific receptors to mediate the hormone signal.

II. Endocrine organs are highly vascularized with fenestrated capillaries and, with the major exception of the thyroid gland, their cells do not show polarity. The nervous and endocrine systems combine to coordinate functions of all body systems and are functionally integrated as the neuroendocrine system.

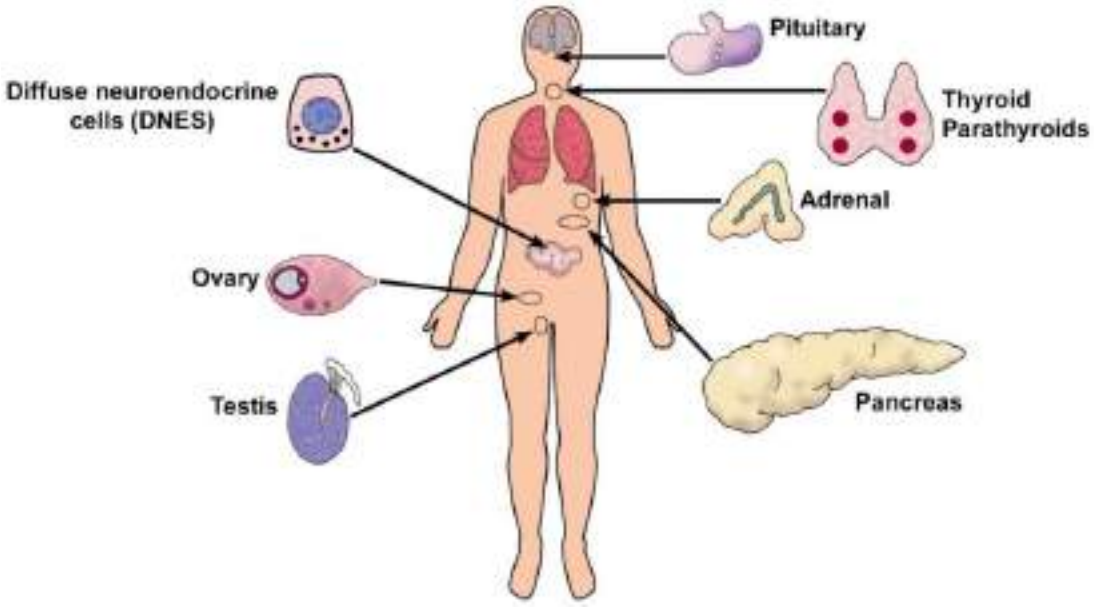

FIGURE 16.1. Components of the endocrine system.

COMPONENTS

I. Individual cells (enteroendocrine cells) ***(images)***

II. Clusters of cells

A. Islets of Langerhans (pancreas)

B. Theca interna (ovary)

C. Interstitial cells (testis)

III. Organs

A. Pituitary

B. Thyroid

C. Parathyroid

D. Adrenal

E. Pineal

HORMONE TYPES

I. Steroids and fatty acid derivatives (cortisol, testosterone)

II. Amino acid derivatives (thyroxine, epinephrine)

III. Peptides and proteins (insulin, growth hormone)

PITUITARY GLAND (HYPOPHYSIS) ***(images)***

ORIGINS OF THE PITUITARY GLAND

I. The pituitary gland consists of two different glands, the adenohypophysis and the neurohypophysis, which are derived embryologically from two distinct tissues.

A. **Adenohypophysis**

1. The adenophypophysis develops from a hollow evagination, **Rathke's pouch**, an outgrowth of ectoderm from the roof of the mouth

2. Rathke's pouch loses its connection with the oral cavity and ascends toward the base of the brain where it contacts the neurohypophysis, growing down from the hypothalamus of the brain.

3. Subdivisions

a. **Pars distalis**. Largest subdivision; forms from the anterior wall of Rathke's pouch, constituting >95% of the adenophypophysis

b. **Pars tuberalis**. Forms a collar of cells around the infundibulum of the

neurohypophysis.

c. **Cystic remnants of Rathke's pouch**. Small cysts persisting from the original cavity of Rathke's pouch

d. **Pars intermedia**. Forms from the posterior wall of Rathke's pouch at the interface of the adenohypophysis with the pars nervosa of the neurohypophysis; these cells also surround small cystic remnants of Rathke's pouch; this subdivision is rudimentary in humans.

B. Neurohypophysis

1. The **neurohypophysis** develops as an outgrowth from the hypothalamus of the diencephalon of the brain, and retains its connection with the brain, abutting the posterior wall of Rathke's pouch.

2. The subdivisions of the neurohypophysis consist of the **infundibulum** and the **pars nervosa**.

II. Pituitary terminology

Terminology based on embryonic origin	Pituitary subdivisions	Clinical terminology
Adenohypophysis	Pars distalis	Anterior lobe of pituitary
	Pars tuberalis	
	Pars intermedia	Posterior lobe of pituitary
Neurohypophysis	Pars nervosa	
	infundibulum	

ADENOHYPOPHYSIS

I. Cell types

Hormone(s)	General Cell Type	Specific Cell Type
GH	Acidophil	Somatotrope
Prolactin	Acidophil	Mammotrope
TSH	Basophil	Thyrotrope
FSH/LH	Basophil	Gonadotrope
ACTH	Basophil	Adrenocorticotrope

A. **Chromophils**

1. **Acidophils**. Hormone-containing granules in the cytoplasm stain with acidic dyes, e.g., eosin

    a. **Somatotropes**. Secrete **somatotropin, (growth hormone, GH)** which promotes growth (anabolic)

    b. **Mammotropes**. Secrete **prolactin** which stimulates milk production

2. **Basophils**. Hormone-containing granules in the cytoplasm of these cells stain with basic dyes, e.g., hematoxylin

    a. **Thyrotropes**. Secrete **thyroid stimulating hormone (TSH)** which stimulates thyroid hormone synthesis and release

    b. **Gonadotropes**. Secrete **luteinizing hormone (LH)** and **follicle stimulating hormone (FSH)** that regulate egg and sperm maturation and sex hormone production. Both hormones are secreted in both males and females. In males LH can be referred to as **interstitial cell stimulating hormone (ICSH)**.

    c. **Adrenocorticotropes**. Secrete **adrenocorticotropic hormone (ACTH)** which regulates glucocorticoid secretion by adrenal gland

B. **Chromophobes**

1. Cells with sparse granule content that do not stain with either hematoxylin or eosin

2. May be degranulated cells or reserve, undifferentiated cells

II. Distribution of cell types in the adenohypophysis

A. Pars distalis contains all five cell types

B. Pars tuberalis contains gonadotropes only

C. Pars intermedia contains basophils; however, their secretions in humans are unclear, although ACTH secretion is a possibility.

III. Regulation of adenohypophyseal secretion

A. Adenohypophyseal hormone secretion is regulated by releasing or inhibitory factors **(neurohormones)** produced by neurons in the hypothalamus. Axons from these neurons terminate on a capillary bed located at the base of the hypothalamus in a region called the median eminence and release their neurohormones into these capillaries.

B. The capillaries anastomose into the **hypophyseal portal vessels** which

travel down the infundibulum and end in a second capillary network within the adenohypophysis.

C. Hypothalamic factors exit this second capillary plexus and either stimulate or inhibit the secretion of hormones from their target acidophil or basophil cells.

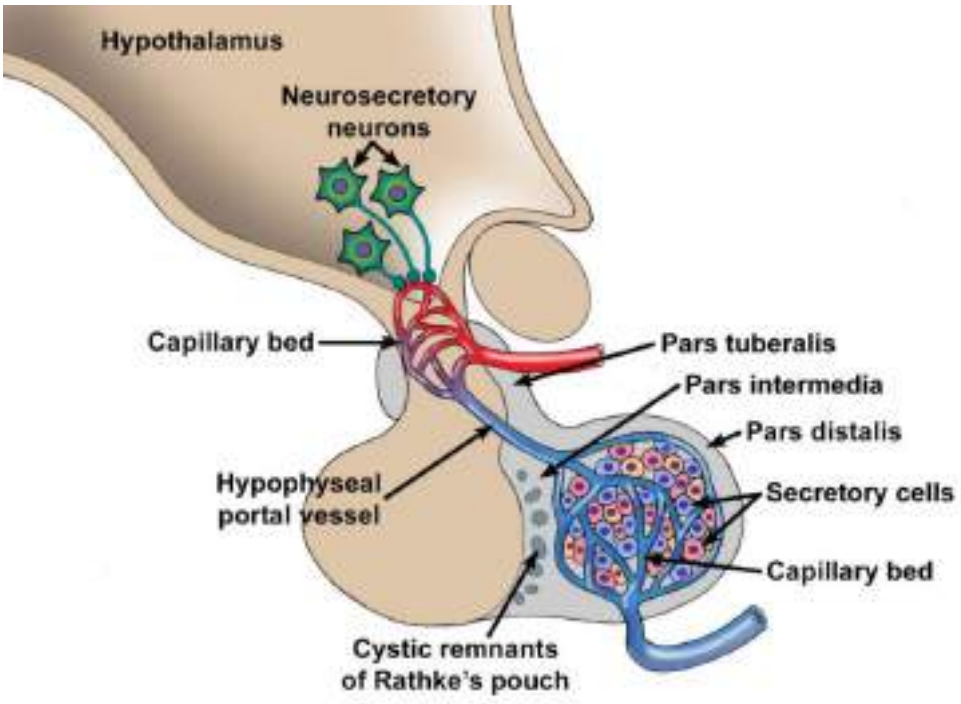

FIGURE 16.2. Structure and regulation of secretion of the adenohypophysis.

NEUROHYPOPHYSIS

I. Components

A. **Infundibulum (hypophyseal stalk)**

1. Extension from the hypothalamus; continuous with the pars nervosa

2. Contains the **hypothalamo-hypophyseal tract** which consists of axons from neurons whose cell bodies are located in the **supraoptic** and **paraventricular nuclei** of the hypothalamus

B. **Pars nervosa**

1. Contains axons and axon terminals of the neurons forming the **hypothalamo-hypophyseal tract**

2. **Herring bodies**. Expanded axon terminals which accumulate secretory granules containing oxytocin or antidiuretic hormone (vasopressin)

    a. **Oxytocin** causes smooth muscle and myoepithelial cell contraction.

    b. **Antidiuretic hormone (ADH)** acts on the kidney tubules to prevent water loss.

3. Also contains "astrocyte-like" cells, called **pituicytes**.

4. No secretory cells are present.

II. Regulation of neurohypophyseal secretion

A. Oxytocin and vasopressin are synthesized by neurons in the hypothalamus, transported down the axons and stored in axons terminals (Herring bodies) in the pars nervosa.

B. Activity in these neurons, in response to physiological signals, causes hormone release (neurosecretion) in a manner similar to release of neurotransmitters.

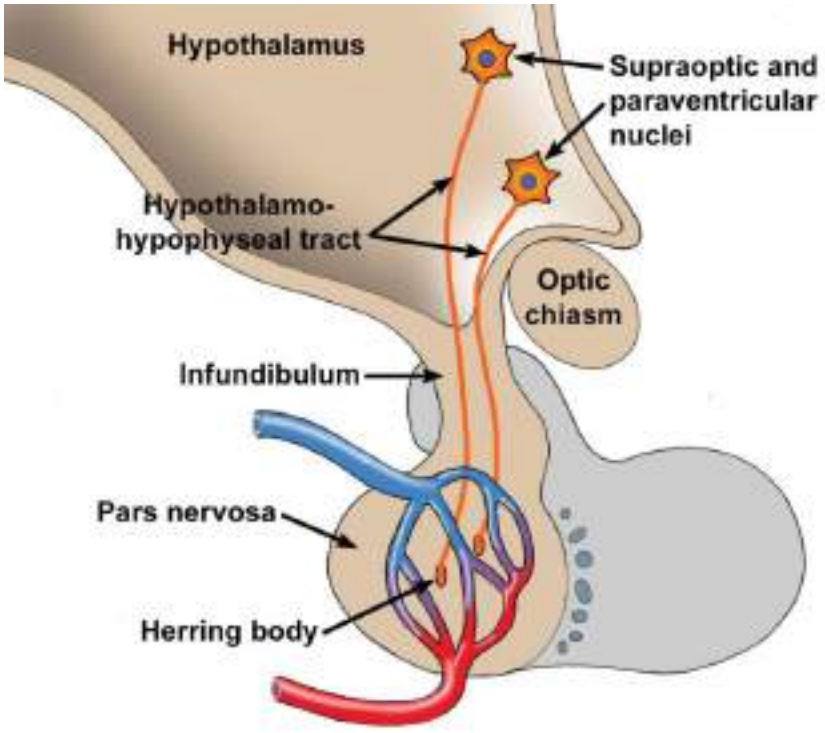

FIGURE 16.3. Structure and regulation of secretion of the neurohypophysis.

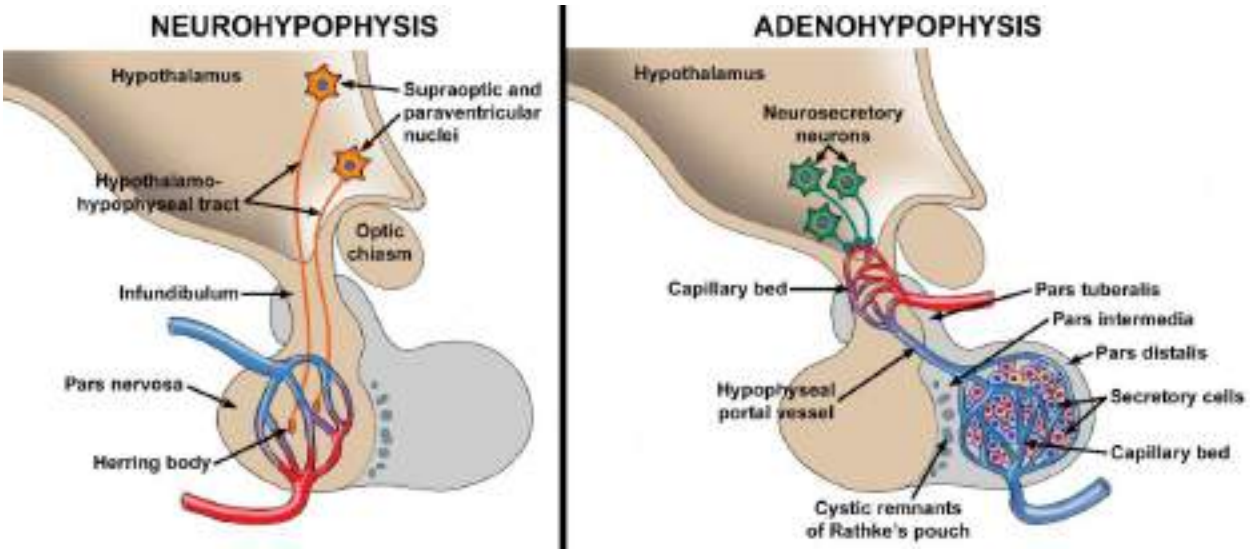

FIGURE 16.4. Comparison of the structure and regulation of secretion of pituitary gland subdivisions.

THYROID GLAND *(images)*

I. The thyroid gland consists of two unique structural and functional subdivisions, the **thyroid follicles** and **parafollicular cells**.

II. **Thyroid follicles**

A. Spherical cysts whose wall is composed of a single layer of follicle cells surrounding a center gel called colloid. Cells have apical and basal surfaces and demonstrate cellular polarity.

B. Follicle cells secrete **thyroglobulin**, a glycoprotein that is stored as colloid in the center of the follicle. The thyroid gland is the only endocrine organ that stores a hormone. When needed, these same follicular cells take up the stored thyroglobulin, transport it across the epithelium and release thyroid hormones into the capillaries surrounding the follicle.

C. Thyroglobulin contains modified tyrosine amino acids that constitute the thyroid hormones, **thyroxine (tetraiodothyronine, T_4)** and **triiodothyronine (T_3)**.

D. Thyroid hormones regulate the basal metabolic rate.

E. The secretion of T_3 and T_4 is controlled by TSH released from the adenohypophysis.

III. **Parafollicular cells (C cells, clear cells)**

A. Are located within the follicular epithelium and in small clusters between follicles

B. Possess secretory granules containing the hormone **calcitonin**, which acts to inhibit bone resorption, lowering blood calcium levels.

C. Belong to the **diffuse neuroendocrine system (DNES)**

D. The secretion of calcitonin is controlled by calcium levels in the blood.

SYNTHESIS AND RELEASE OF THYROID HORMONES

I. Follicle cells synthesize and secrete thyroglobulin from their apical surfaces into the follicle lumen where it is stored. The follicle lumen is an extracellular compartment and, thus, secretion of thyroglobulin constitutes the exocrine secretion of the follicle cells and accounts for the polarity of the cells.

II. The tyrosines of thyroglobulin are iodinated in the follicle lumen and rearranged to form the thyroid hormones (T_3 and T_4), which are modified tyrosines that are retained in the primary structure of thyroglobulin.

III. The iodinated thyrogobulin is resorbed by pinocytosis into the follicle cells where it is hydrolyzed, liberating T3 and T4.

IV. T_3 and T_4 are released from the basolateral surfaces of the follicle cell and enter the blood stream.

V. Active and inactive follicles

A. **Active follicle**. Follicle cells are cuboidal to columnar and are involved with both secretion and resorption of thyroglobulin.

B. **Inactive follicle**. Follicle cells are squamous, reflecting the paucity of secretory organelles and the lack of synthetic and uptake activity.

PARATHYROID GLANDS *(images)*

I. The **parathyroid glands** are four small, spherical glands that are embedded in the posterior surface of the thyroid gland.

II. Cell types

A. **Chief cell**

1. Major cell type, arranged in cords or clumps

2. Small polyhedron-shaped cells with secretory granules visible only with electron microscope

3. Secrete **parathyroid hormone (PTH)** which increases blood calcium levels, through increased osteoclast activity

4. The secretion of PTH is controlled by calcium levels in the blood.

B. **Oxyphil cell**

1. Large cell may appear singly or in clumps

2. Heterochromatic nucleus and abundant eosinophilic cytoplasm, due to numerous mitochondria

3. No secretory granules

4. Function is unclear.

ADRENAL GLANDS *(images)*

I. Structure

A. Paired glands, each located at the superior pole of a kidney; consist of two distinct subdivisions with different embryological origins

B. Subdivisions

1. **Cortex**. Derived from mesoderm and constitutes the major steroid-producing gland

2. **Medulla**. Derived from neural crest and is a major source of epinephrine and norepinephrine neurohormones

C. Surrounded by a dense **capsule**

II. Cortex

A. Composed of steroid-secreting cells, whose features include:

1. Abundant smooth endoplasmic reticulum

2. Mitochondria with **tubular cristae** in the zona fasciculata and the zona reticularis; **shelf-like cristae** in the zona glomerulosa

3. Numerous lipid droplets filled with cholesterol, precursor for steroid hormones

4. Secretion is by diffusion with no hormone storage.

B. Zonation

1. **Zona glomerulosa**

a. Located immediately beneath the capsule

b. Cells arranged in round clusters

c. Secretes **mineralocorticoids, e.g., aldosterone**

2. **Zona fasciculata**

a. Middle layer, largest cortical zone

b. Cells arranged in rows perpendicular to the capsule alternating with wide-diameter, fenestrated capillaries

c. Secretes **glucocorticoids** and **androgens**

d. The secretion of glucocorticoids is controlled by ACTH released from the adenohypophysis.

3. **Zona reticularis**

a. Forms deepest layer of the cortex

b. Cells arranged as anastomosing cords

c. Same secretions as zona fasciculata, **glucocorticoids** and **androgens**

III. Medulla

A. Composed of **chromaffin cells**

1. Modified adrenergic neurons without axons or dendrites; represent sympathetic ganglion cells

2. Polyhedral cells containing abundant dense-core, secretory granules

B. Chromaffin cells synthesize and release epinephrine and norepinephrine, which are routinely released in small quantities. Under stress, the autonomic nervous system stimulates greater production and release.

PINEAL GLAND (EPIPHYSIS CEREBRI) ***(images)***

I. Structure

A. Small conical-shaped gland; develops from the roof of the diencephalon and remains attached by a short pineal stalk

B. Surrounded by a **capsule** composed of **pia mater**

1. Connective tissue septa derived from the pia mater penetrate the gland and subdivide it into indistinct lobules.

2. Sympathetic axons and blood vessels enter the gland with the septa.

C. Cells

1. **Pinealocytes**

a. Major cell type, represent modified neurons

b. Euchromatic nucleus, spherical to ovoid, with a prominent nucleolus

c. Cytoplasm not evident with conventional stains; however, silver staining reveals that the cell generally has two or more extensions similar to neuronal processes.

d. Processes end in association with capillaries.

e. Secrete **melatonin**, an indoleamine hormone

2. **Interstitial cells**

a. Minor cell type, similar to astrocytes in the brain

b. Nucleus is elongated and more heterochromatic than that of pinealocytes.

c. Possess long processes with intermediate filaments

d. Located among groups of pinealocytes and in the connective tissue septae

D. **Corpora araneacea ("brain sand")**

1. Globular, basophilic accumulations of calcium phosphates and carbonates in the interstitial space

2. Radio-opaque in X-ray images and, thus, often used as indicators of

midline deflection of the brain resulting from pathological conditions

II. Secretion

A. Major hormone secreted is melatonin which regulates diurnal (circadian) light-dark cycles and seasonal rhythms.

B. Melatonin is secreted during darkness; secretion is inhibited by light.

C. Retinal stimulation by light is relayed to the pineal via sympathetic innervation from the superior cervical ganglion.

CHAPTER 3

EPITHELIAL TISSUES

GENERAL CONCEPTS

I. Classification of epithelial tissues

A. **Lining and covering epithelia**

1. Form the boundary between external environment and body tissues

a. Cover body surfaces (e.g., the epidermis of the skin) and lines the lumens of internal organs that open to the exterior of the body

b. Line body cavities (e.g., peritoneal cavity) and covers the exterior of organs that project into these cavities

c. Line blood and lymph vessels

2. Cell shape and number of layers correlate with the function of the epithelium.

B. **Glandular (secretory) epithelia**

1. Develop from a lining or covering epithelium by invagination into the underlying connective tissue

2. Form exocrine and endocrine glands.

II. General features of all epithelial tissues

A. Highly cellular (sparse intercellular space)

B. Numerous intercellular junctions for attachment and anchorage

C. Avascular

D. High proliferative capacity, especially in epithelial membranes, to replace continual sloughing of cells from free surface

E. Most rest on a **basement membrane**. ***(images)***

1. The basement membrane is composed of a **basal lamina** and a **reticular lamina**.

a. The basal lamina is secreted by the epithelial cells and consists of the **lamina lucida** and the **lamina densa**. A similar structure is also present in muscle and nervous tissue, where it is referred to as an **external lamina**.

b. The reticular lamina is secreted by fibroblasts located in the underlying connective tissue.

2. Functions of the basement membrane

a. Provides support and attachment for the epithelial cells

b. Acts as a selective diffusion barrier

F. Free and basal surfaces of epithelia

1. **Basal surface** contacts the basal lamina of the basement membrane.

2. **Free surface** interfaces with the external environment or spaces within the body.

3. **Polarity**. A polarized cell is one that exhibits contrasting properties or structures on opposite sides of the cell. Because epithelial tissues face a free surface, the function of the apical surface is often very different from that at the base of the cell. This diversification is reflected by the non-homogeneous distribution of organelles.

LINING AND COVERING EPITHELIAL TISSUES

METHOD OF CLASSIFICATION

I. Classification by number of layers

A. **Simple epithelium**

1. One cell layer thick

2. All cells rest on the basement membrane (basal surface) and all cells face the free surface.

B. **Stratified epithelium**

1. More than one cell layer thick

2. Only the deepest layer of cells contact the basement membrane and only the superficial-most cells have a free surface.

3. Named according to the shape of the cells at the free surface.

II. Classification by shape of surface cells

A. **Squamous**

1. Cells are much wider than tall, resembling a "fried egg."
2. Nucleus is highly flattened.

B. **Cuboidal**

1. Cells are of equal height and width.
2. Nucleus is spherical.

C. **Columnar**

1. Cells are much taller than they are wide.
2. Nucleus is oval shaped, generally located in the mid to lower portions of the cell.

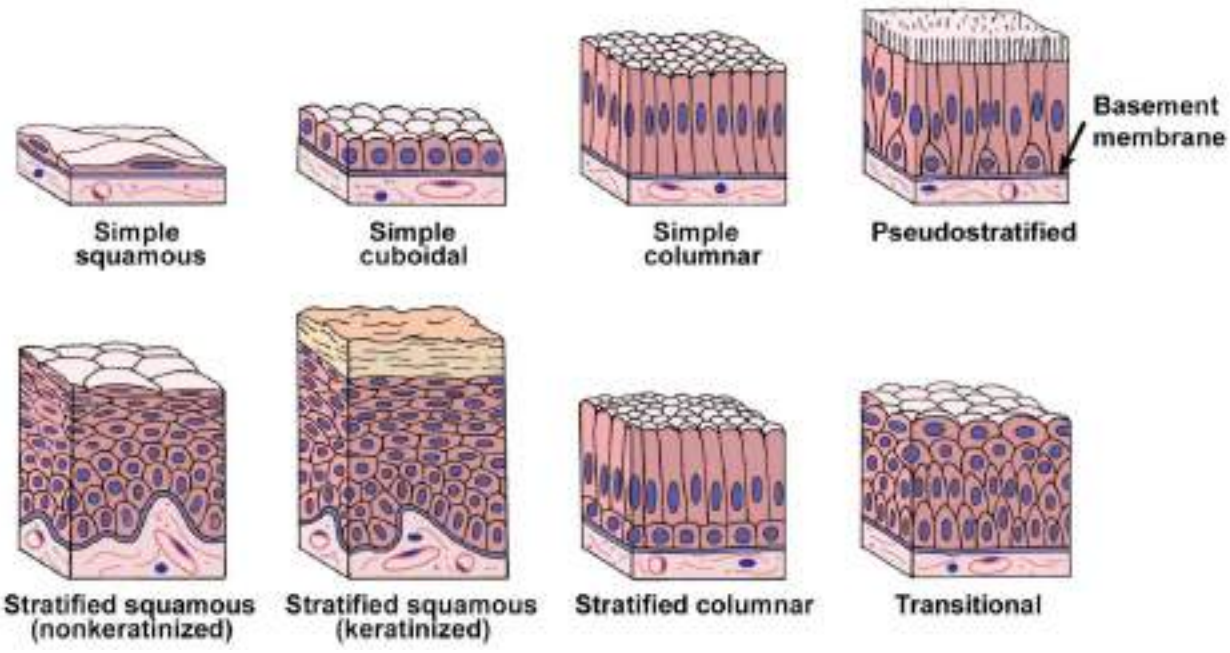

FIGURE 3.1. Types of lining and covering epithelia.

TYPES OF LINING AND COVERING EPITHELIUM

I. Simple epithelial tissues ***(images)***

A. **Simple squamous**

1. Allows for rapid diffusion across the epithelium

2. Forms the lining of blood vessels, alveoli of the lungs, and internal body cavities

B. **Simple cuboidal**

1. Lines and absorbs

2. Forms the walls of ducts and tubules

C. **Simple columnar**

1. Lines and absorbs

2. Forms the lining of the intestines and gall bladder

D. **Pseudostratified**

1. Cells are of various heights. All cells rest on the basement membrane, but only the tallest cells reach the free surface. Variation in height of the cells and the location of nuclei give the appearance of a stratified epithelium. Frequently ciliated.

2. Provides protection and surface transport when ciliated

3. Forms the lining of much of the respiratory tract and much of the male reproductive system

II. Stratified epithelial tissues ***(images)***

A. **Stratified squamous**

1. Protects from physical abrasion and prevents desiccation

2. Types

a. **Nonkeratinized (moist)**. Lining of wet cavities, including the mouth, esophagus, rectum, and anal canal; surface cells are nucleated and living.

b. **Keratinized (dry)**. Epidermis of the skin; surface cells are nonliving.

B. **Stratified cuboidal/columnar**. Lines the larger ducts of exocrine glands.

C. **Transitional**

1. Protective function; constructed to expand with distension of the hollow organs it lines

2. Unique to the urinary system; lines the urinary bladder and ureter

SURFACE SPECIALIZATIONS and CELL JUNCTIONS

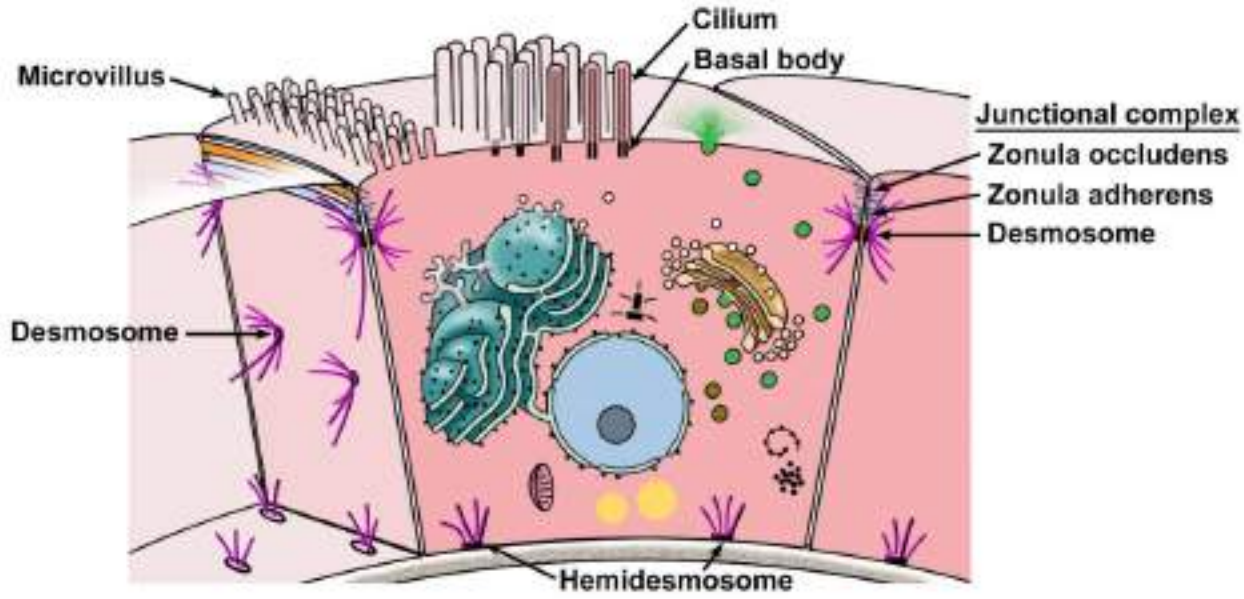

FIGURE 3.2. Cell junctions and surface specializations.

SURFACE SPECIALIZATIONS

I. **Microvilli *(images)***

A. Finger-like extensions from the free surface of the cell, about 1 micron in height

B. Are usually present in large numbers on each cell and, collectively, are called a **brush or striated border**

C. Contain a core of actin microfilaments

D. Are relatively non-motile

E. Increase surface area for absorption

F. Prominent on cells lining the digestive tract and proximal tubules in the kidney

II. **Stereocilia** ***(images)***

A. Large, non-motile microvilli; not cilia

B. Contain a core of actin microfilaments

C. Increase surface area

D. Present on cells lining the epididymis and ductus deferens in the male reproductive tract

III. **Cilia** ***(images)***

A. Multiple hair-like extensions from free surface of the cell; 7-10 microns in height

B. Highly motile; beat in a wave-like motion

C. Function to propel material along the surface of the epithelium (e.g., in the respiratory system and the oviduct of the female reproductive system)

D. Core of a cilium is called the **axoneme**, in which nine pairs of microtubules surround two central, individual microtubules (9 + 2 arrangement).

E. The axomene of each cilum originates from a **basal body** that is located at the apex of the cell and is composed of nine triplets of microtubules.

CELL JUNCTIONS ***(images)***

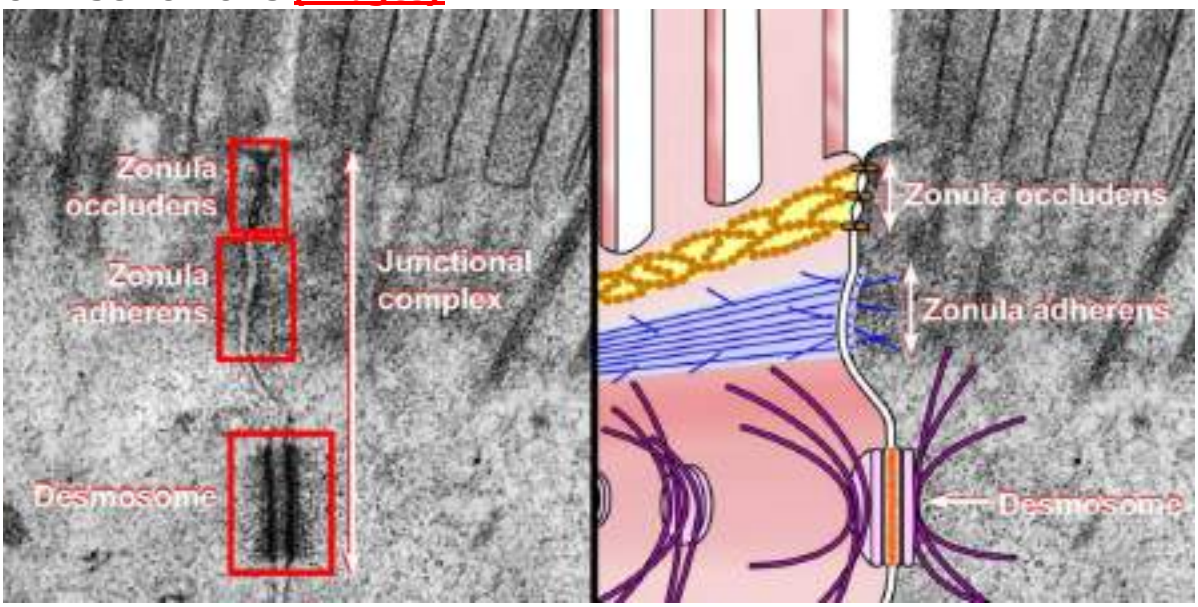

FIGURE 3.4. Cell junctions and surface specializations.

I. Specialized structures of the plasma membrane that:

   A. Attach and anchor cells

   B. Establish apical and basolateral membrane domains by sealing adjacent plasma membranes

   C. Provide channels for ionic and metabolic coupling

II. Not restricted to epithelial cells; cell junctions occur, however, in large number in epithelial tissues to resist the physical forces acting on the cells.

III. Types

   A. **Tight junction (zonula occludens)**

      1. Belt-like, barrier junction around apex of the cell

      2. Provides close apposition of adjacent plasma membranes and occludes the intercellular space

      3. Functions

         a. Prevents diffusion of material between the intercellular space and the lumen of the organ

         b. Establishes apical and basolateral membrane domains in the cell by preventing the lateral migration of proteins in the plasma membrane

   B. **Adherent junctions**

      1. Attach cells to each other or anchor them to the basal lamina; no fusion of the plasma membrane

      2. Types of adherent junctions

         a. **Belt desmosome (zonula adherens)**. Belt-like junction that encircles the apex of the cell like a barrel strap and is located immediately beneath the zonula occludens; serves to attach adjacent cells together; associated with actin filaments.

         b. **Spot desmosome (macula adherens)**. Disk-like junctions scattered over the surface of the cell, which are paired with similar structures in adjacent cells; associated with intermediate filaments (e.g., keratin filaments in epithelial cells).

c. **Hemidesmosome**. Represents a "half desmosome"; these junctions anchor the basal surface of the cell to the basal lamina.

C. **Junctional complex**. Consists of the zonula occludens, zonula adherens, and desmosomes; because these structures cannot be resolved as separate structures at the light microscopic level, they appear as a single, bar-shaped, dark region at the apical corners of adjacent cells. The term **terminal bar** was used by early microscopists to define the zonula occludens and zonula adherens at the light microscopic level.

D. **Gap junction**

1. Gap junctions consist of **connexons**, six transmembrane proteins clustered in a rosette that form a central pore. Connexons from adjacent cells abut one another, forming a continuity between cells.

2. Provides metabolic and electrical continuity (coupling) via the pores between cells

GLANDULAR EPITHELIAL TISSUES

GENERAL CONCEPTS

I. Develop from or within a lining or covering epithelium

II. Secretory cells may

A. Differentiate but remain in the lining epithelium

B. Invaginate into the underlying connective tissue and remain attached to the lining epithelium

C. Invaginate into the underlying connective tissue but lose their connection to the epithelium

EXOCRINE VS. ENDOCRINE GLANDS

I. Major classification of glands, which is based on the method by which their secretory product is distributed

II. **Exocrine glands**

A. Secretory products are released onto an external or internal epithelial surface, either directly or via a duct or duct system.

B. Secretory cells display polarized distribution of organelles.

III. **Endocrine glands**

A. No ducts; secretory products are released directly into the extracellular fluid where they can affect adjacent cells (paracrine secretion) or enter the bloodstream to influence cells throughout the body (endocrine secretion).

B. No polarization of organelles, except the thyroid gland and enteroendocrine cells of the digestive tract

C. Secretory products are called hormones.

METHODS OF PRODUCT RELEASE FROM GLANDULAR CELLS

I. **Merocrine**. Secretory product is released by exocytosis of contents contained within membrane-bound vesicles. This method of release is used by both exocrine and endocrine glands. Examples are digestive enzymes from pancreatic acinar cells and insulin from pancreatic islet cells.

II. **Apocrine**. Secretory material is released in an intact vesicle along with some cytoplasm from the apical region of the cell. This method of release is used by exocrine glands only. An example is the lipid component of the secretory product of the mammary gland.

III. **Holocrine**. Entire cell is released during the secretory process. Cells that are released may be viable (oocyte or sperm) or dead (sebaceous glands). This method of release is used by exocrine glands only.

IV. **Diffusion**. Secretory product passes through the cell membrane without the formation of secretory granules. Examples are steroid hormones. This method of release is used by endocrine glands only.

TYPES OF SECRETORY PRODUCTS

I. Exocrine glands

A. **Mucus**. Thick, viscous, glycoprotein secretion

1. Secretory cells are usually organized into tubules with wide lumens.

2. Cytoplasm appears vacuolated, containing mucigen that, upon release, becomes hydrated to form mucus.

3. Nucleus is flattened and located in the base of the cell.

B. **Serous**. Thin, watery, protein secretion

1. Secretory cells are usually organized into a flask-shaped structure with a narrow lumen, called an acinus.

2. Cytoplasm contains secretory granules.

3. Nucleus is round and centrally located in the cell.

C. Special

1. **Lipid**. Oily secretion (sebum) from sebaceous glands and lipid portion of milk from the mammary gland.

2. **Sweat**. Hypotonic, serous secretion that is low in protein content.

3. **Cerumen**. A waxy material formed by the combination of the secretory products of sebaceous and ceruminous glands with desquamated epidermal cells in the auditory canal

II. Endocrine glands

A. **Derivatized amino acids**, e.g, thyroxine and epinephrine

B. **Peptides and proteins**, e.g., insulin and oxytocin

C. **Steroids**, e.g., testosterone and cortisol

CLASSIFICATION OF EXOCRINE GLANDS *(images)*

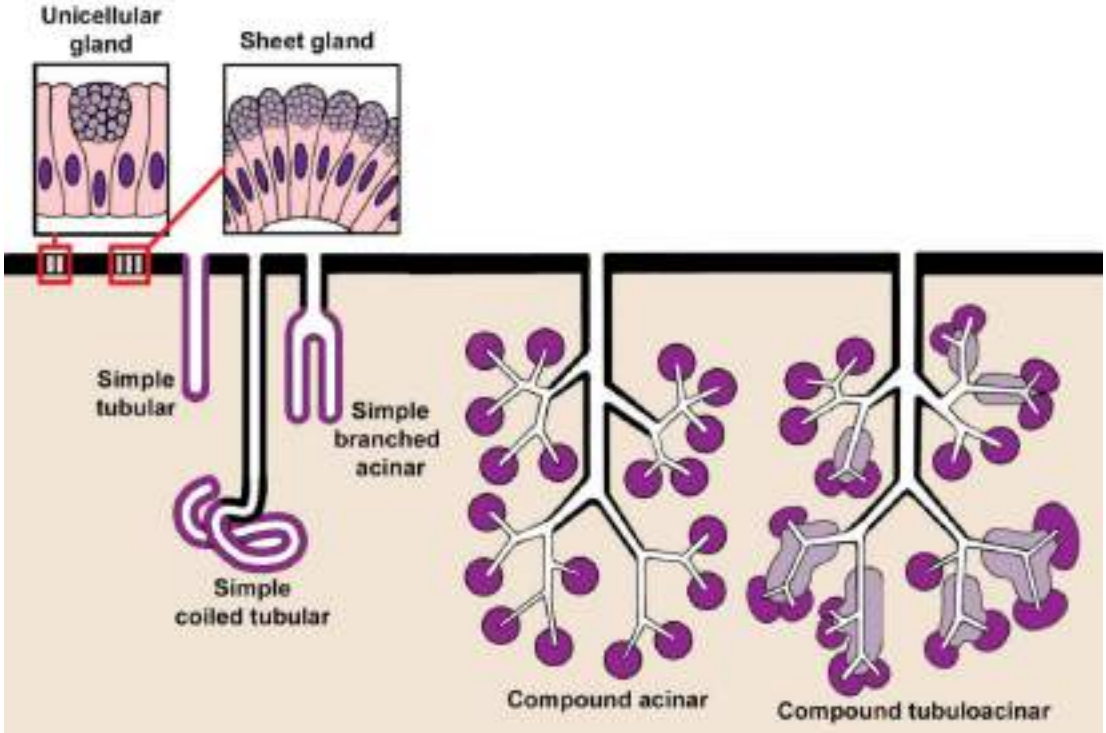

FIGURE 3.4. Types of glands based on their morphology.

I. **Unicellular glands**. Individual cells located within an epithelium, such as **goblet cells** that secrete mucus

II. Multicellular glands

A. **Sheet gland**. Composed of a surface epithelium in which every cell is a mucus-secreting cell. A sheet gland is unique to the lining of the stomach.

B. The remaining multicellular glands are classified according to:

1. The shape(s) of the secretory units

a. Presence of **tubules** only

b. Presence of only **acini** (singular, **acinus**) or **alveoli** (singular, **alveolus**) (these two terms are synonymous), which are flask-shaped structures

c. Presence of both tubules and acini

2. The presence and configuration of the duct

a. **Simple**. No duct or a single, unbranched duct is present.

b. **Compound**. Branching duct system

3. Classification and types of multicellular glands

a. **Simple tubular**. No duct; secretory cells are arranged like a test tube that connects directly to the surface epithelium (e.g., intestinal glands).

b. **Simple, branched tubular**. No duct; tubular glands whose secretory units branch (e.g., fundic glands of stomach)

c. **Simple, coiled tubular**. Long unbranched duct; the secretory unit is a long coiled tube (e.g., sweat glands).

d. **Simple, branched acinar (alveolar)**. Secretory units are branched and open into a single duct (e.g., sebaceous glands).

e. **Compound tubular**. Branching ducts with tubular secretory units (e.g., Brunner's gland of the duodenum)

f. **Compound acinar (alveolar)**. Branching ducts with acinar secretory units (e.g., parotid salivary gland)

g. **Compound tubuloacinar (alveolar)**. Branching ducts with both tubular and acinar secretory units (e.g., submaxillary salivary gland)

SPECIAL FEATURES OF SOME EXOCRINE GLANDS

I. **Serous demilunes**. Consist of a "cap" of serous cells around the end of a mucous tubule; appear half-moon shaped in section

II. **Myoepithelial cells**. Resemble smooth muscle cells in their fine structure but are of epithelial origin; prominent in sweat and mammary glands, they surround secretory units, lying inside the basement membrane, and aid in the expulsion of secretory products from the gland.

DUCT SYSTEM OF COMPOUND, EXOCRINE GLANDS *(images)*

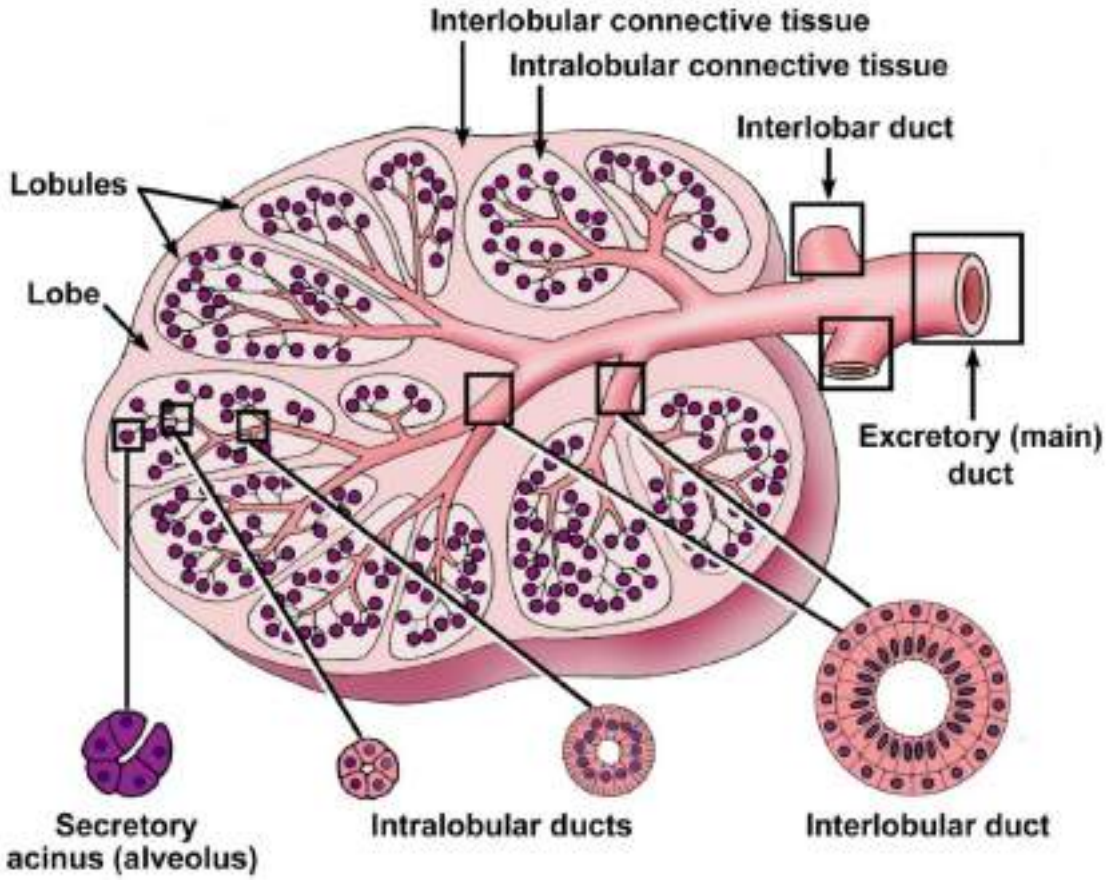

FIGURE 3.5. Structure of a compound gland.

I. **Intralobular ducts**. Contained within a lobule; simple cuboidal to columnar epithelium

II. **Interlobular ducts**. Receive numerous intralobular ducts; located in the connective tissue between lobules; stratified columnar epithelium

III. **Excretory (main) duct**. Macroscopic duct draining the entire gland

ENDOCRINE GLANDS (SEE ALSO CHAPTER 16)

I. No ducts; generally cells are not polarized

II. Occurrence

   A. Unicellular (e.g., enteroendocrine cells of the digestive tract); these cells do show polarity because they are located within an epithelium and secrete away from the free surface of the epithelium.

   B. Small clusters of cells (e.g., islet of Langerhans in pancreas)

   C. Organs (e.g., thyroid gland, adrenal gland)

III. Secretory cells of multicellular glands are usually arranged as plates or cords. The thyroid gland, where the cells form fluid-filled spheres, is an exception to this pattern.

IV. Highly vascular with fenestrated capillaries

V. Secretory products are called hormones. Hormones can be:

   A. Derived from amino acids (e.g, thyroxine and epinephrine)

   B. Peptides and proteins (e.g., insulin and oxytocin)

   C. Steroids (e.g., testosterone and cortisol); steroid-secreting cells display mitochondria with tubular cristae and contain large amounts of lipid droplets and smooth endoplasmic reticulum.

VI. Secrete by the merocrine or diffusion methods only

CHAPTER 19

EYE

GENERAL CONCEPTS

I. The eyes are complex photoreceptive organs located in the bony orbits of the skull. Movement of the eye is accomplished by a set of extrinsic ocular muscles, which insert on the outer surface of the globe.

II. Each eye consists of image-forming structures, a photoreceptive retina, and a fibrous globe to provide support.

III. The eye is protected by an eyelid, a moveable fold of skin that covers the anterior surface of the globe.

EYELID *(images)*

I. Protective covering of the eye.

II. Components

A. Covered on its outer surface by thin skin that possesses eyelashes at the margin of the eyelid

B. **Tarsal plate**. Region of dense fibrous and elastic connective tissues within the eyelid that provide support

C. Contains the **obicularis oculi muscle**

D. **Meibomian glands**. Specialized sebaceous glands embedded in the tarsal plate, whose secretions add to the tear film to reduce evaporation

E. **Palpebral conjunctiva**. Lines the inner surface, consisting of a stratified columnar epithelium with goblet cells; the conjunctiva is reflected onto the globe as the bulbar conjunctiva, which is continuous with the **corneal epithelium**.

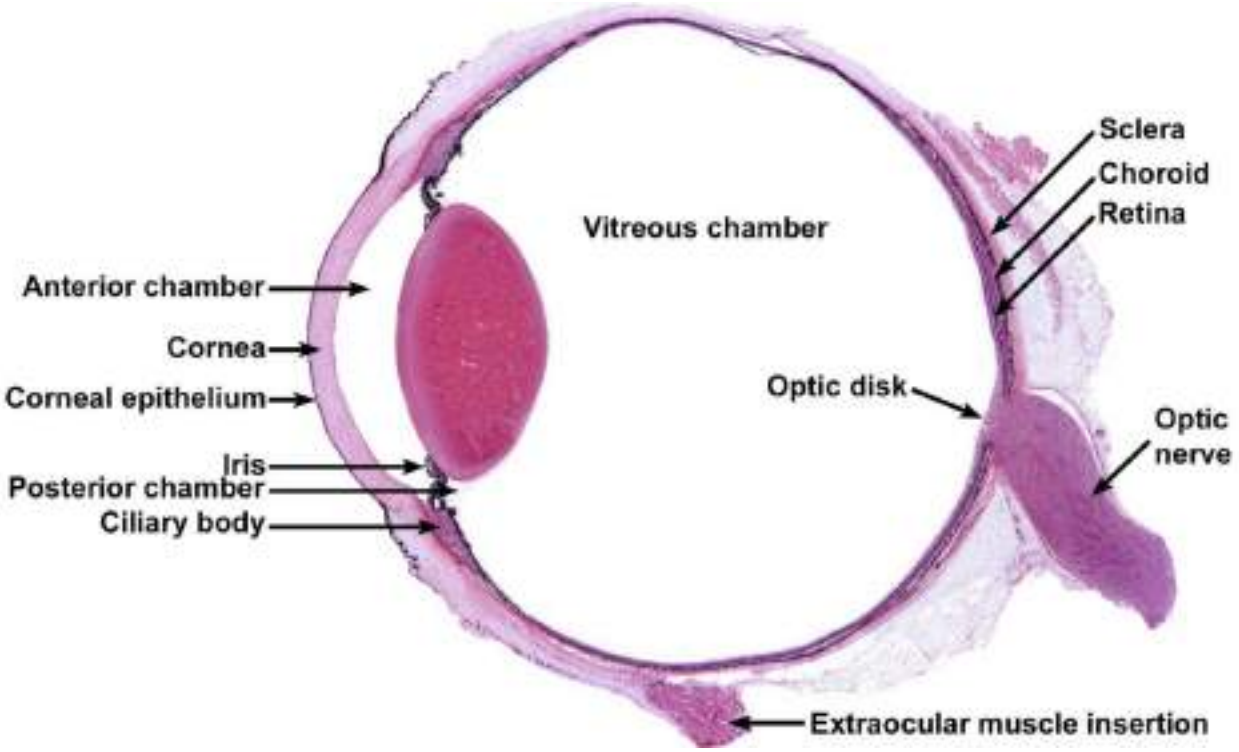

FIGURE 19.1. Midsagittal section of the eyeball.

EYEBALL (GLOBE) ***(images)***

I. Composed of three layers or tunics

   A. **Fibrous tunic** consisting of the sclera and cornea

   B. **Vascular tunic or uveal tract** consisting of the iris, ciliary body, and choroid

   C. **Neural tunic** consisting of the retina

II. Contains three chambers

   A. **Anterior chamber** is the space between the cornea and the iris, filled with *aqueous humor* fluid.

   B. **Posterior chamber** lies between the iris anteriorly and the lens, ciliary body, and zonule fibers posteriorly; filled with aqueous humor

   C. **Vitreous chamber** is located behind the lens and is filled with a gelatinous substance called the **vitreous body**.

FIBROUS TUNIC OF THE EYE (OUTER TUNIC)

I. **Sclera**

A. Opaque layer composed of dense, irregular connective tissue; forms the outer layer of the posterior four-fifths of the globe

B. Gives shape and provides support for the globe

C. Provides insertion points for extraocular muscles

II. **Cornea**

A. Anterior continuation of the sclera, covering the anterior one-fifth of the eye

B. Transparent and avascular; transparency results from the ordered arrangement of its collagen fibers and low state of tissue hydration.

C. Convex curvature aids in focusing light (refraction).

D. Layers (anterior to posterior)

1. **Corneal epithelium**. Covers the anterior surface of the cornea; composed of a moist, stratified squamous epithelium that is continuous with the bulbar conjunctiva at the *limbus*

2. **Bowman's membrane**. Acellular collagenous layer beneath the corneal epithelium

3. **Stroma**. Multiple layers of parallel collagen fibers constitute the majority of the cornea. The collagen fibers in each layer are arranged at about right angles to adjacent layers. The highly ordered arrangement of these fibers contributes to the transparency of the cornea.

4. **Descemet's membrane**. Thickened basal lamina of the corneal endothelium

5. **Corneal endothelium**. Simple squamous epithelium covering the posterior surface of the cornea; regulates the hydration state of the stroma

III. **Corneo-scleral junction (limbus)**

A. Transition zone between the cornea and the sclera

B. Bowman's membrane ends and the corneal epithelium thickens at this junction.

C. **Trabecular meshwork**. Irregular channels in the stroma that are lined by endothelium. Drains the aqueous humor from the anterior chamber to maintain proper intraocular pressure. The channels of the trabecular meshwork merge to form the **canal of Schlemm**, a ring-like sinus that encircles the limbus and drains into the venous system.

VASCULAR TUNIC (UVEAL TRACT) OF THE EYE (MIDDLE TUNIC)

I. Choroid

A. Highly vascular, cellular layer lying inside the sclera; this layer is richly pigmented due to its large number of **melanocytes**. Its inner portion is the **choriocapillary layer**, which contains large numbers of small vessels and capillaries and serves a nutritive function for the retina.

B. **Bruch's membrane**. A thin layer separating the retina from the chori-ocapillary layer; represents the combined basal laminae of the capillary endothelium and the pigment epithelium of the retina and an intervening network of elastic and collagen fibers

II. Ciliary body

A. Anterior expansion of the choroid forming a ring that encircles the lens; appears triangular in cross-section

B. Composed of a core of connective tissue and muscle; lined on its vitreal surface by two layers of columnar cells, an inner pigmented epithelium and an outer layer of non-pigmented cells. These two layers of columnar cells form the non-sensory retina and represent the attenuated anterior part of the sensory layer of the retina.

C. **Ciliary processes**

1. Ridge-like extensions from the ciliary body

2. **Zonule fibers**. Emerge from between the processes and attach to the lens capsule

3. The aqueous humor is produced by the epithelium of the ciliary processes.

D. **Ciliary muscles**. Smooth muscle fibers that insert on the sclera and ciliary body; contraction of circularly arranged fibers releases tension on the **zonule fibers**, allowing the lens to assume a more spherical shape, thus providing for focusing on near objects (**accommodation**). Contraction of radially oriented smooth muscle fibers results in flattening of the lens, thus providing for focusing on far objects.

III. **Iris**

A. Disc-shaped structure that arises from the anterior margin of the ciliary body; separates anterior and posterior chambers and partially covers the lens

B. Composed of loose connective tissue that is covered on its anterior surface by an incomplete layer of pigment cells and fibroblasts. Its posterior surface is covered by a double layer of pigmented epithelial cells.

C. **Pupil**. Central opening in the iris; its diameter is regulated by contraction of two sets of intrinsic smooth muscle in the iris.

1. **Dilator pupillae muscle**. Derived from the more anterior, pigmented epithelial layer; consists of radially oriented cells whose contraction widens the aperture of the pupil

2. **Constrictor pupillae muscle**. Consists of circularly oriented smooth muscle fibers surrounding the pupil; contraction of these fibers decreases the diameter of the pupil.

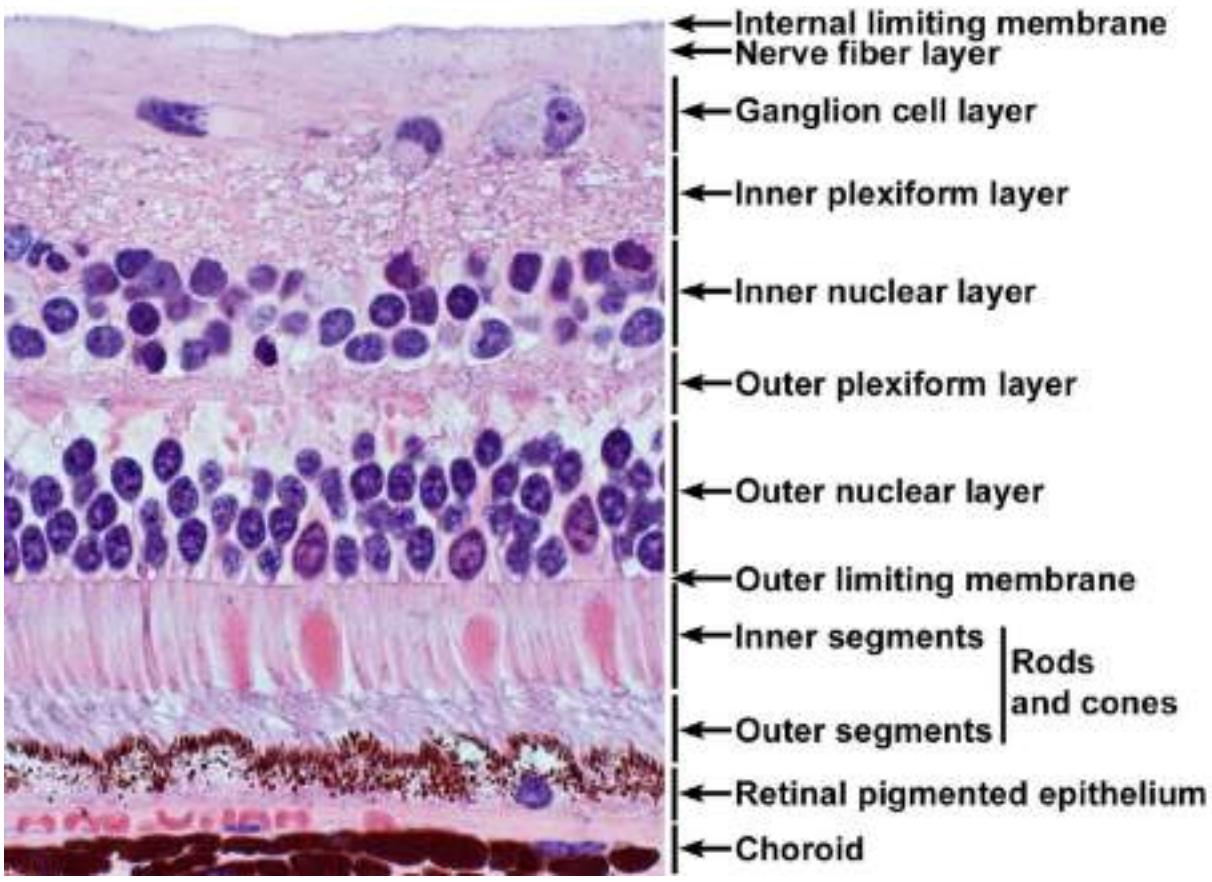

FIGURE 19.2. Layer of the retina

RETINA - INNER TUNIC *(images)*

I. Inner-most of the three layers, forming a cup-shaped structure. The posterior portion is photosensitive and extends forward to the ciliary body, terminating as the **ora serrata**. The nonphotosensitive anterior portion is reduced in thickness and number of layers and forms the posterior lining of the ciliary body and the posterior lining of the iris.

II. The photosensitive portion contains the photoreceptors, which transduce light into nervous impulses, and neurons, which perform the initial integration of the visual signals.

III. Overview of retinal cytoarchitecture

A. Basic plan of the **retina** consists of a three-cell pathway

1. **Rods** and **cones**. Photoreceptors that transduce light energy into neural activity and form the **photoreceptor layer**; their nuclei are located in the **outer nuclear layer**.

2. **Bipolar cells**. Synapse with rods and cones; nuclei are located in the **inner nuclear layer**.

3. **Ganglion cells**. Synapse with bipolar cells; cell bodies are located in the **ganglion cell layer**; axons from these cells form the **optic nerve fiber layer** as they pass toward the **optic disc**, head of the optic nerve.

B. Regions of synaptic integration

1. **Outer plexiform layer**. Location of synapses of rods and cones with bipolar cells

2. **Inner plexiform layer**. Location of synapses of bipolar cells and ganglion cells

IV. Layers of the retina–from outer to inner

A. Composed of 10 layers. The naming of the layers is based on their position relative to the path of neural conduction (from outer to inner), not the path of light (from inner to outer).

B. **Pigment epithelium**

1. Cytoplasm contains numerous **melanin granules** to absorb light and reduce reflection

2. Columnar epithelial cells with apical microvilli whose bases are adherent to

Bruch's membrane

3. Cells form a cylindrical sheath that surrounds the apical tips of the photoreceptors; these sheaths aid in phagocytosis and digestion of membranous discs shed by the photoreceptors.

C. **Photoreceptor layer**

1. Composed of rods and cones

2. Rods are sensitive to low light intensity, outnumber cones and are located throughout the retina

3. Cones are less numerous than rods, sensitive to high intensity light and respond to color. Cones provide greater visual acuity and are concentrated in the **fovea centralis**.

4. **Outer segment**. Contains flattened, membranous discs that contain the visual pigments rhodopsin (rods) and iodopsins (cones).

5. **Inner segment**. Separated from the outer segment by a constriction, contains the major synthetic and energy-producing organelles.

D. **External limiting membrane**. Not a true membrane; formed by adherent junctions of Mueller cells, modified astrocytes, with the photoreceptors

E. **Outer nuclear layer**. Location of the nuclei of rods and cones

F. **Outer plexiform layer**. Region of synaptic contacts between photoreceptor axons and bipolar cell dendrites

G. **Inner nuclear layer**. Location of cell bodies of bipolar cells. Also present are additional neurons, amacrine and horizontal cells.

H. **Inner plexiform layer**. Location of synaptic contacts between bipolar cell axons and ganglion cell dendrites.

I. **Ganglion cell layer**. Location of cell bodies of ganglion cells

J. **Optic nerve fiber layer**. Layer formed by the unmyelinated axons of the ganglion cell axons that pass toward the **optic disc**, the head of the optic nerve, where they exit to form the **optic nerve** (cranial nerve II).

K. **Internal limiting membrane**. Formed by the basal portions of Mueller cells

V. **Fovea centralis**. Region of the retina providing greatest visual acuity, consists entirely of cones; other retinal layers are displaced centrifugally to allow for an unimpeded path for the light to reach the photoreceptors.

VI. **Optic disc** ("blind spot"). Region composed only of axons from retinal ganglion cells as they exit from the retina through the sclera to form the optic nerve

LENS *(images)*

I. Biconcave, transparent, and elastic

II. Suspended by radially oriented zonule fibers that extend from the ciliay body to insert into the lens capsule

III. Structure of the lens

A. **Lens capsule**. A thickened basal lamina, produced by the subcapsular epithelium, surrounds the entire lens.

B. **Subcapsular epithelium**. Simple cuboidal epithelium, present only on the anterior surface of the lens; apical surfaces of the cells are directed toward the center of the lens.

C. **Lens fibers**. Derived from cells of the subcapsular epithelium primarily in the equatorial region of the lens; lens fibers are highly differentiated cells that lose their organelles and become filled with crystallin proteins.

IV. Contraction of the circularly arranged ciliary muscle releases tension on the zonule fibers, allowing the lens to assume a more spherical shape which provides for focusing on near objects (accommodation). Contraction of the radially oriented ciliary muscles causes the lens to flatten for focusing on distant objects.

CHAPTER 18

FEMALE REPRODUCTIVE SYSTEM

GENERAL CONCEPTS

I. Components

   A. Paired ovaries

   B. Paired oviducts or Fallopian tubes

   C. Uterus

   D. Vagina

II. Functions

   A. Produces female germ cells, ova (singular, ovum)

   B. Produces female sex hormones, estrogen, and progesterone

   C. Receives sperm

   D. Site of fertilization

   E. Transports female germ cells, sperm, and conceptus

   F. Houses and nourishes the developing fetus during pregnancy

   G. Expels baby at parturition

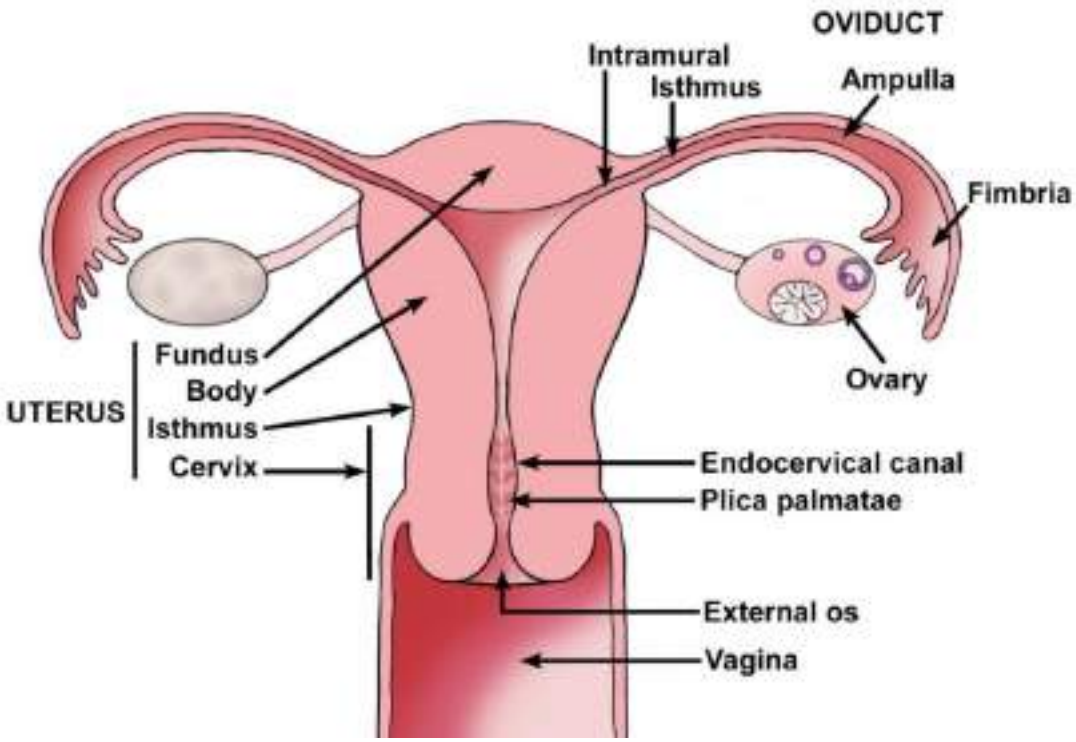

FIGURE 18.1. Schematic representation of the female reproductive system.

OVARY

GENERAL ORGANIZATION *(images)*

I. Flattened, ovoid, paired glands

   A. Exocrine function. Maturation and release of oocytes, developing female germ cells

   B. Endocrine function. Secretion of estrogen and progesterone

II. Subdivisions

   A. **Cortex**

      1. Covered with a serosa

         a. **Germinal epithelium**. Simple cuboidal epithelium, unique mesothelium

         b. **Tunica albuginea**. Underlying, dense connective tissue

      2. Contents (exact contents depend on age of the ovary and the stage of the ovarian cycle)

a. **Follicles**. Spheres of epithelial cells surrounding an oocyte. Multiple follicles progress through a series of stages until a single follicle ruptures to release the secondary oocyte at ovulation. Follicles secrete estrogen during the first half of the ovarian cycle.

b. **Corpus luteum**. Formed from the wall of the ovulating follicle beginning just before and following ovulation of the oocyte. The corpus luteum secretes progesterone and estrogen and is present during the second half of the ovarian cycle.

c. **Atretic follicles**. Degenerating follicles that are not ovulated

d. **Corpus albicans**. Degenerating corpus luteum

B. **Medulla**. Inner region composed of connective tissue, blood vessels, nerves

OOGENESIS

I. Oogenesis is a multistaged process by which a diploid somatic cell, an oogonium, in the fetal ovary becomes a haploid ovum in the adult after fertilization occurs.

II. Stages

A. **Oogonia** in the fetal ovary divide mitotically to form diploid, primary oocytes that are located in primordial follicles. Unlike spermatogonia, oogonia reproduce themselves only during early gestation and, thus, no oogonia persist at birth.

B. **Primary oocytes** immediately begin the first meiotic division, which arrests in prophase. Primordial follicles, each containing a primary oocyte, are the only follicles present from birth until puberty, when selected follicles go through a series of changes during each ovarian cycle, resulting in ovulation.

C. Formation of a **secondary oocyte**: a primary oocyte in a Graafian follicle completes meiosis I during the hours preceding ovulation in most ovarian cycles, producing a secondary oocyte and a nonfunctional polar body. The secondary oocyte begins meiosis II but arrests in metaphase; this is the oocyte that is ovulated.

D. An **ovum**, the mature, haploid germ cell, is formed along with a second polar body only if fertilization occurs.

COMPARISON OF OOGENESIS WITH SPERMATOGENESIS *(image)*

I. Gametogenesis, the formation of haploid (1N) ova and sperm, is a multistaged

process that includes both mitosis and meiosis. While chromosomal events producing sperm (spermatogenesis) and ova (oogenesis) are similar, cytoplasmic stages, the timing of divisions and the number of gametes formed is different between the male and the female.

II. Stages

A. Mitosis

1. Beginning at puberty in males, diploid precursor spermatogonial cells divide to form diploid spermatogonia. Spermatogonia, in turn, divide by mitosis, renewing their own cell line, as well as producing cells that enter meiosis. In contrast in the female, before birth diploid precursor oogonial cells divide to form diploid oogonia. Oogonia divide mitotically, again before birth, forming only cells that enter meiosis, thus depleting their own cell line. Oogonia are not self-renewing and, at birth, no oogonia remain in the ovary.

2. In males, cytokinesis of spermatogonia and primary and secondary spermatocytes is incomplete, and thus, cells remain attached to each other. In females, cytokinesis is complete.

B. Meiosis. In the male, primary and secondary spermatocytes complete both meiotic stages, producing four functional, haploid spermatozoa of equal size from each diploid spermatogonia. In contrast, in the female, when primary and secondary oocytes complete meiosis, only a single, functional, haploid ovum is formed, along with two or three small, nonfunctional satellite cells (polar bodies).

C. Maturation

1. In males, after the completion of meiosis, spermatids undergo morphological changes, transforming themselves from spherical cells to tadpole-shaped spermatozoa, and breaking their cytoplasmic connections. No such maturation process occurs in the female.

2. In females, the completion of meiosis II, with the formation of an ovum, occurs only after fertilization. If fertilization does not occur, the secondary oocyte is destroyed or degenerates.

3. Fusion of the haploid male and female nuclei produces a diploid zygote, reconstituting the full complement of chromosomes.

III. Spermatogenesis occurs throughout the reproductive life of a male, producing millions of sperm during this span. Oogenesis lasts for only 30-40 years in the female and produces only a minimal number of ova, because completion of oogenesis is dependent on fertilization.

FOLLICLES *(images)*

I. **Primordial follicle**

A. Contains a **primary oocyte**

B. **Follicular cells** form a simple squamous epithelium around the oocyte.

C. Is the only follicle present until puberty

II. Primary follicles

A. **Early primary follicle (unilaminar)**

1. Contains a primary oocyte

2. Follicular cells form a simple cuboidal or columnar epithelium around the oocyte.

B. **Late primary follicle (multilaminar)**

1. Contains a primary oocyte

2. Follicular cells form a stratified epithelium around the oocyte.

3. **Zona pellucida**, formed by both the oocyte and adjacent follicular cells, is a thick glycoprotein band surrounding the oocyte. Forms early in follicle development but easily visualized at this stage.

4. **Theca folliculi**, a layer located outside the basement membrane of the follicular cells, is formed by the differentiation of the surrounding multipotential stromal cells.

III. **Secondary follicle (antral follicle)**

A. Contains a primary oocyte

B. Follicle cells increase in size and number and produce a follicular liquid.

C. Composition

1. Antral spaces form as follicular liquid accumulates between follicular cells. Multiple antral spaces eventually coalesce to form a single **antrum**.

2. The **granulosa layer (granulosa cells or stratum granulosum)** is formed by follicular cells surrounding the antrum. These cells convert androgens, produced in theca interna, into estrogen.

3. The **cumulus oophorus** is a hillock of granulosa cells in which the primary oocyte is embedded. The innermost layer of cumulus cells, immediately surrounding the oocyte, forms the **corona radiata**.

4. **Zona pellucida**

5. Theca folliculi develops into:

    a. **Theca interna**, located immediately outside the basement membrane of the follicular cells, is composed of cells that secrete the steroid hormone androgen.

    b. **Theca externa**, composed of multipotential connective tissue cells, resembles a layer of flattened fibroblasts and lies outside the theca interna. The theca externa serves as a reserve cell source for the theca interna.

D. Although a group of follicles begins follicular development, usually only a single secondary follicle progresses to the mature follicle stage in a single ovarian cycle.

E. Follicular growth and maturation are influenced by follicle stimulating hormone (FSH), secreted by the pituitary gland, and estrogen, aromatized by granulosa cells from androgen produced by the theca interna.

IV. **Mature (Graafian) follicle**. The follicle that will rupture, ovulating a secondary oocyte. Present only during the day preceding ovulation. Changes occurring during the time it is present include:

A. Increase in follicular liquid greatly increases antral and follicle size; follicle will reach a diameter of about 2.0 cm.

B. Granulosa and theca interna cells begin formation of **corpus luteum**.

C. Enlarged follicle bulges from the ovarian surface, thinning the ovarian tissue covering the follicle and forming a **stigma**.

D. Oocyte and surrounding cumulus oophorus detach from the granulosa layer and lie free in the antral space.

E. Meiosis I is completed with the formation of a **secondary oocyte** and **first polar body**. Meiosis II arrests in metaphase.

F. **Ovulation**. Day 14 of ovarian cycle

1. The Graafian follicle ruptures at the stigma, releasing the haploid secondary oocyte, polar body, cumulus oophorus, follicular liquid, and blood.

2. Oocyte and the surrounding cumulus are transported into the oviduct to the ampulla to await fertilization. Fertilization triggers the completion of meiosis II and the formation of an ovum.

3. The follicle wall and theca interna continue their conversion into a corpus luteum.

4. Ovulation is stimulated by a surge of luteinizing hormone (LH) from the pituitary gland.

V. **Atretic follicles**

A. The process of oocyte/follicular atresia begins before birth and continues throughout the life of a woman. Of the 2 million primordial follicles and their primary oocytes present at birth, only about 450,000 oocytes/follicles remain at puberty and only about 450 of those will be ovulated. The remaining follicles degenerate, thereby producing more atretic than "normal" follicles.

B. Atresia can occur at any stage of follicular development and will begin in different layers of the follicle or oocyte depending on the follicle's stage of development. Therefore, many varieties of atretic follicles can be seen.

CORPUS LUTEUM *(images)*

I. The **corpus luteum** is a large, spherical, infolded body functional during the second half of the ovarian cycle.

II. Formation and life span

A. Initially, bleeding from capillaries in the theca interna into the follicular lumen leads to formation of the **corpus hemorrhagicum** with a central clot.

B. The corpus luteum isformed by differentiation of the granulosa and theca interna cells in the Graafian follicle before and after ovulation.

C. Its formation is stimulated by luteinizing hormone (LH) secreted by the pituitary gland

D. The life span of the corpus luteum is finite, lasting about 12 days during the average cycle, during days 14-26.

E. Composed of:

1. **Granulosa lutein cells**. Form from cells in the granulosa layer; typical steroid-secreting cells; major component of the corpus luteum

2. **Theca lutein cells**. Form from theca interna cells; typical steroid-secreting cells but smaller than granulosa lutein cells; remain at the outer boundary of the corpus luteum surrounding the granulosa lutein cells and extending into the infoldings of the corpus luteum

F. Secretes progesterone and estrogen

G. If pregnancy occurs, placental hormones maintain the corpus luteum, and it is known as the corpus luteum of pregnancy. This structure is functional for the first trimester of pregnancy.

III. **Corpus albicans**. Degenerating stage.

A. Results from the degeneration of the corpus luteum

B. Consists of a white mass of scar tissue composed of much collagenous material and scattered fibroblasts

CYCLICITY OF OVARY-BASED ON AN AVERAGE 28-DAY CYCLE

I. **Follicular phase** (days 1-13). Follicles are differentiating and secreting estrogen. Follicles are developing while menstruation (days 1-4) is occurring.

II. **Ovulation** (day 14). Graafian follicle ruptures, releasing secondary oocyte.

III. **Luteal phase** (days 15-28). Corpus luteum is the functional ovarian structure, secreting progesterone and estrogen. Hormone secretion diminishes after day 26.

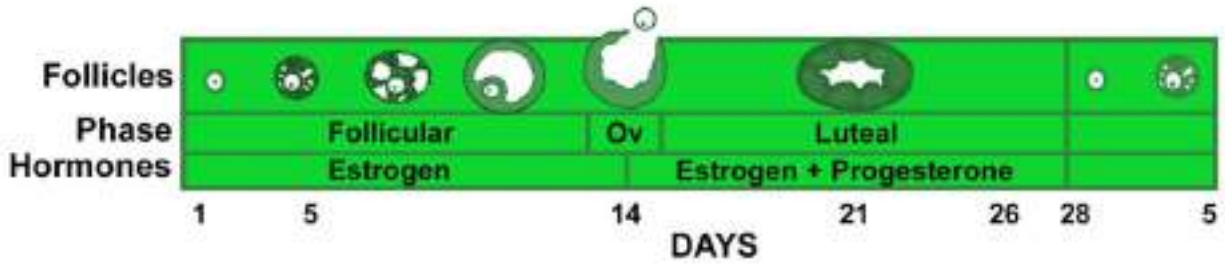

FIGURE 18.2. The ovarian cycle

OVIDUCT *(images)*

I. Subdivisions

A. Paired, 12-cm-long tubes that have four subdivisions.

1. **Infundibulum**. Funnel-shaped, free end with finger-like fimbria embracing the ovary

2. **Ampulla**. Thin walled, lateral two-thirds; fertilization occurs here near its junction with the isthmus

3. **Isthmus**. Thicker walled, medial one-third

4. **Intramural (interstitial)**. Within uterine wall; lumen is continuous with uterine lumen.

II. Structure

A. **Mucosa**

1. Shows gradations from infundibulum to intramural subdivisions

2. Exhibits complex mucosal folds that are most elaborate in the infundibulum and are sparse in the intramural subdivision

3. Epithelium. **Simple columnar** composed of **ciliated cells**, that are most abundant in the infundibulum, and **secretory cells**, that are most abundant in the intramural portion

4. Muscularis mucosae is lacking.

B. **Submucosa** is continuous with lamina propria, forming a continuous connective tissue layer.

C. **Muscularis externa** has poorly defined inner circular and outer longitudinal smooth muscle layers, which are thinnest in the infundibulum and thickest in the intramural portion.

D. **Serosa**. Covers the outer surface except in the intramural portion

UTERUS

GROSS ANATOMY

I. A single, pear-shaped, and pear-sized organ

II. Subdivisions

A. **Fundus**. Domed portion above entrance of oviducts

B. **Corpus or body**. Major portion of the uterus

C. **Isthmus**. Constricted portion at junction of cervix and body

D. **Cervix**. Located above and within the vagina, defining supravaginal and

vaginal portions

HISTOLOGICAL ORGANIZATION OF THE BODY AND FUNDUS *(images)*

I. **Perimetrium**. Outermost layer, a serosa, covers the upper and posterior regions only; an adventitia surrounds the remaining portions that lie adjacent to the urinary bladder.

II. **Myometrium**. A thick, well-vascularized band of smooth muscle that is arranged in ill-defined layers. The myometrium forms the major portion of the uterus and is equivalent to a muscularis externa.

III. **Endometrium**. Mucosa.

A. Components

1. Epithelium is **simple columnar**, some with cilia.

2. **Lamina propria (endometrial stroma)** contains multipotential (stromal) cells and abundant ground substance.

3. Simple tubular glands

B. Zonation

1. **Functional zone (stratum functionalis)**. Luminal two-thirds that is sloughed during menstruation

2. **Basal zone (stratum basalis)**. Firmly attached to the myometrium and retained during menstruation. Cell growth from this zone restores functional zone following menstruation.

ARTERIAL SUPPLY TO ENDOMETRIUM

I. **Basal (straight) arteries**. Remain in and supply basal zone.

II. **Spiral arteries**. Located at the junction of the basal and functional zones, spiral arteries extend into and supply the functional zone and a capillary plexus beneath the surface epithelium of the uterus. Early in the menstrual cycle, spiral arteries are nearly straight, but they become highly coiled later in the cycle.

III. A capillary plexus lies under the surface epithelium.

ENDOMETRIAL CHANGES IN THE BODY AND FUNDUS DURING MENSTRUAL CYCLE

I. Coordinated with ovarian cycle and controlled by its hormones; approximately 28 days long ***(image)***

II. Phases of uterine menstrual cycle ***(images)***

A. **Menstrual phase**. Days 1-5, the clinical beginning of the cycle; however, this phase actually marks the end of the cycle. At the end of menstruation the functional zone has been sloughed and only the basal zone remains.

B. **Proliferative phase** (estrogenic). Days 6-14

1. Ovarian follicles are growing and secreting estrogen.

2. The functional zone proliferates and regenerates from the basal zone.

a. Proliferation of epithelial and stromal cells thickens the endometrium.

b. Glands are initially straight but become slightly wavy toward the end of the phase.

c. Spiral arteries are initially straight, but coil as the endometrium develops and thickens.

C. **Secretory phase** (luteal). Days 14-26

1. Corpus luteum is present and functional.

2. Uterine glands are actively secreting glycogens and glycoproteins by day 20 or 21 when implantation could occur.

3. Endometrial changes leading up to day of implantation

a. Glands enlarge and become tortuous, coiled, and secretory.

b. Spiral arteries lengthen, are highly coiled, and readily visible.

c. Stromal cells become **(pre)decidual cells** (about day 24).

i. Large, pale cells, with glycogen and lipid, located under the surface epithelium and around spiral arteries

ii. If pregnancy occurs, these cells are called **decidual cells** and form the decidua, the maternal placenta.

iii. If pregnancy does not occur, these same cells are called predecidual cells and they are sloughed with menses.

D. Premenstrual phase. (ischemic portion of secretory phase) Days 26-28

1. Estrogen and progesterone secretion from the ovarian corpus luteum decreases.

2. Compression of the endometrium, resulting from lack of hormones from the corpus luteum, causes:

   a. Constriction of the spiral arteries, which results in ischemia in the overlying tissue in the functional zone.

   b. The ischemia causes the endometrium to become necrotic and disrupted

   c. Spiral arteries reopen and blood flows into the ischemic tissue, resulting in bleeding from the spiral arteries into the stroma.

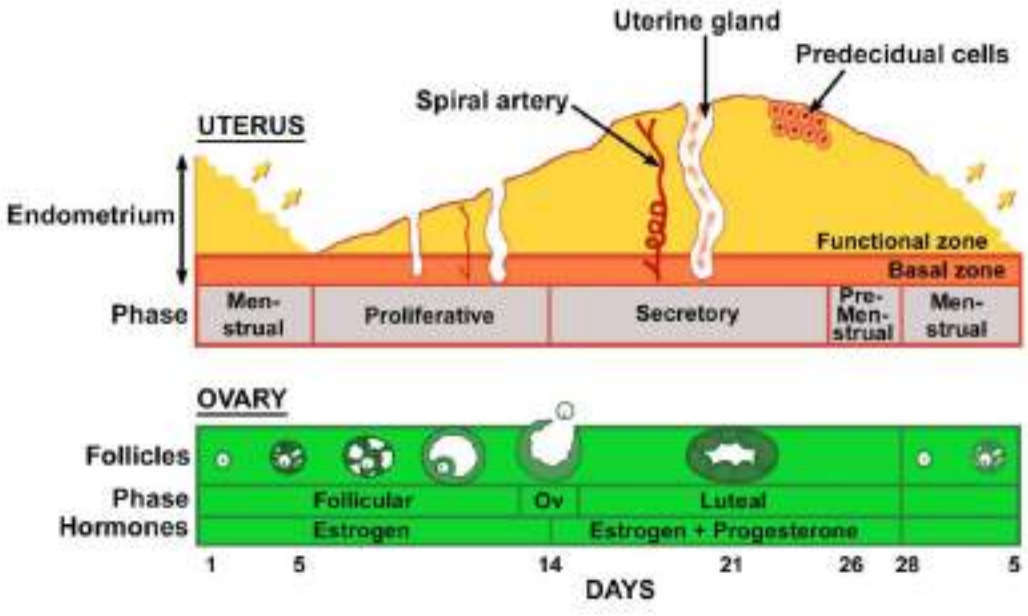
   d. Cycles of compression and reopening of the arteries leads to degeneration of the functional zone and menstruation.

E. **Menstrual phase**. Days 1-5

1. The functional zone becomes necrotic and is sloughed as menses.

2. Menstrual flow contains blood, tissue fragments, and uterine fluids.

3. Only the basal zone remains, from which the functional zone will be



regenerated.

FIGURE 18.3. Comparison of menstrual and ovarian cycles

CERVIX *(images)*

I. The cervix is the most inferior portion of the uterus, beginning above and extending into the vagina.

II. **Endocervix**

A. Surrounds the **endocervical canal**

A. Structure

1. Mucosa

a. Simple columnar epithelium with cilia and many mucus-secreting cells

b. Lamina propria is filled with epithelial folds, the **plica palmatae**, that are lined with mucus-secreting cells.

c. **Nabothian cysts** occur when a fold becomes occluded.

2. Remainder of cervix consists of connective tissue with some smooth muscle.

B. Cyclic changes and functions of the cervix

1. Mucosa is not sloughed during menstruation. Spiral arteries are absent.

2. Cyclic changes in the cervical mucus

a. At mid-cycle, secretions are abundant and the molecules are linearly arranged, facilitating the movement of sperm through the cervix and/or into the plica palmatae for storage. The alkalinity of the cervical mucus neutralizes the low vaginal pH, providing a more favorable environment for spermatozoa.

b. At other times during the cycle, cervical mucus is more viscous, making sperm penetration difficult.

III. **Ectocervix**

A. Portion of the cervix that protrudes into the vagina

B. Covered by **moist stratified squamous epithelium**. The junction of this epithelium with the simple columnar epithelium of the endocervical canal is abrupt and is called the squamo-columnar junction

C. **External os**. Opening of the endocervical canal into the vagina.

VAGINA *(images)*

I. Structure

A. **Mucosa**

1. Epithelium. **Stratified squamous nonkeratinized**, cells accumulate glycogen; when shed, it is metabolized by vaginal bacteria to lactic to maintain acidic environment.

2. Lamina propria. No glands present, rich with numerous blood vessels and elastic fibers.

3. Muscularis mucosae is lacking.

4. **Rugae** (folds) allow for expansion.

B. **Submucosa** is continuous with the lamina propria, forming a single connective tissue layer.

C. **Muscle layers**

1. Inner circular and outer longitudinal smooth muscle layers intertwine.

2. Skeletal muscle surrounds the vaginal orifice.

D. **Adventitia** of loose connective tissue

II. Cyclic Changes

A. The epithelium synthesizes and accumulates glycogen, becoming thick and proliferative by midcycle.

B. Bacterial breakdown of the glycogen produces lactic acid, creating an acidic environment in the vagina which is protective against bacterial infection.

PLACENTA

GENERAL CONSIDERATIONS *(images)*

I. An apposition or fusion of membranes of the fetus (chorion) with maternal uterine mucosal tissue (the decidua) to produce hormones and to exchange gases and nutrients

II. Function

A. Provides exchange of respiratory gases between maternal and fetal circulations

B. Provides nutrients for and removes wastes from the conceptus

C. Secretes hormones

D. Transports some macromolecular materials (e.g., viruses, IgG, alcohol)

BLASTOCYST

I. A **blastocyst** is the stage of the embryo that implants into the uterus about day 20 or 21 of the menstrual cycle.

II. Composition

A. **Trophoblast cells** form the peripheral rim of the fluid-filled blastocyst cavity and will develop into the fetal portion of the placenta.

B. **Inner cell mass**, an eccentrically located cluster of cells inside the trophoblast at one pole of the blastocyst, develops into the embryo.

CHORION, THE FETAL PLACENTA

I. The **chorion**, derived from trophoblast, is composed of extraembryonic connective tissue and two cell layers derived from the trophoblast, called the cytotrophoblast and the syncytiotrophoblast.

II. Formation of the fetal placenta

A. Forms within the 23 days following ovulation

B. **Trophoblast** erodes into the maternal endometrium at implantation and immediately differentiates into:

1. **Cytotrophoblast.** Inner (toward embryo) single layer that gives rise to the syncytiotrohoblast

2. **Syncytiotrophoblast.** Multinucleated, outer syncytium formed from the cytotrophoblast; aggressively invades the uterine endometrium

C. **Lacunae**, separated by columns of syncytiotrophoblast, develop in the syncytiotrophoblast and coalesce, becoming filled with maternal blood from the spiral arteries. After the formation of villi, lacunae are called

intervillous spaces.

D. **Tertiary (definitive) chorionic villi**

1. The final in a series of villi that protrude from the syncytiotrophoblast columns into the lacunae, increasing the surface area of the placenta that is exposed to maternal blood.

2. Formed by invasion of syncytiotrophoblast columns by cytotrophoblastic cells and then by fetal connective tissue. Finally, fetal blood vessels invade into and form within the fetal connective tissue.

3. Composition. From internal to external

    a. Core of **fetal connective tissue** with fetal blood vessels

    b. **Cytotrophoblast**

        i. Large, discrete cells with large, euchromatic nuclei form a single layer around the connective tissue core.

        ii. Changes during pregnancy

            (a) Early pregnancy. Cytotrophoblast forms a continuous layer beneath the syncytiotrophoblast.

            (a) Late pregnancy. Cytotrophoblast layer thins and is even lacking in some areas, thus decreasing the thickness of the barrier through which nutrients/wastes must pass.

    c. **Syncytiotrophoblast**

        i. Covers outer surface of the villus, facing the intervillous spaces filled with maternal blood.

        ii. Composed of a single cell (syncytium), possessing multiple nuclei; formed by fusion of cytotrophoblastic cells

        iii. Possesses microvilli and abundant organelles associated with both protein and steroid hormone production

        iv. Functions

            (a) Forms part of the interhemal barrier (barrier between fetal and maternal blood vessels)

            (a) Secretes a variety of hormones, such as human chorionic gonadotrophin (HCG), human placental lactogen (HPL,

somatomammotropin), human placental thyrotropin (HPT), and estrogen and progesterone

4. Alterations during pregnancy

    a. Early pregnancy. Villi are thick, with a few, thick branches.

    b. Late pregnancy. Villi are much more slender, with profuse branching, thus increasing surface area.

E. **Trophoblastic shell**

1. Outer rind of the fetal placenta abutting the maternal deciduas

2. Composed of cytotrophoblast positioned between the syncytiotrophoblast and the external maternal decidua.

3. Formed by cytotrophoblast cells growing through and then spreading out beneath the syncytiotrophoblast columns

THE DECIDUA, THE MATERNAL PLACENTA

I. The **decidua** is formed from endometrial stromal cells that differentiate into decidual cells beginning about day 24 of the menstrual cycle (about 3 days post implantation).

II. Partitioned into three subdivisions, named according to the position of each in relation to the developing conceptus

A. **Decidua basalis**. Underlies the implanted conceptus (beneath trophoblastic shell), forming the maternal portion of the functional placenta

B. **Decidua capsularis**. Covers the luminal surface of the conceptus, separating it from the uterine lumen; will eventually fuse with decidua parietalis of the opposite side of the uterus, obliterating the uterine lumen

C. **Decidua parietalis** lines the remainder of the uterus.

III. Maternal cotyledons

A. **Maternal cotyledons** form a "lobe" of the placenta, easily identifiable on the maternal surface of the placenta as domed-shaped protrusions from the placenta.

B. Up to 35 lobes are present.

C. Malformations (discrepancies) of these cotyledons, when examined at

delivery, can indicate fetal abnormalities.

PLACENTAL BLOOD FLOW

I. Fetal

A. **Umbilical arteries** are two in number and travel from the fetus through the umbilical cord to the placenta, carrying blood that is high in carbon dioxide and low in nutrient content. Umbilical arteries branch into capillaries within the tertiary villi.

B. Fetal capillaries are located in the tertiary chorionic villi (definitive villi).

C. Fetal veins from the capillaries anastomose to form the single **umbilical vein** that returns oxygen-rich, nutrient-rich blood to the fetus.

II. Maternal

A. **Spiral arteries** penetrate trophoblastic shell and spurt blood into intervillous spaces, bathing villi.

B. Branches of uterine veins carry blood away from the intervillous spaces.

III. Placental interhemal membrane

A. The **placental interhemal membrane** separates maternal (in the intervillous spaces) and fetal blood (in capillaries within tertiary villi) supplies, which normally do not mix.

B. Beginning in the fetal capillary, this barrier consists of:

1. Capillary endothelial cell (of villus) and its basement membrane

2. Fetal connective tissue of villus (usually lacking in late pregnancy)

3. Cytotrophoblast (may be lacking in late pregnancy) and its basement membrane

4. Syncytiotrophoblast

BREAST

I. Organization of the breast ***(images)***

A. Each breast is a collection of 15-20 separate **mammary glands**, which are modified sweat glands.

B. Each gland or lobe of the breast is further subdivided into lobules.

C. Each gland in its functional state is classified as a **compound tubulo-alveolar gland**

D. Each gland has its own **lactiferous duct***,* which empties at the nipple.

II. Organization of mammary glands

A. **Stroma***.* Connective tissue framework of the breast

1. **Interlobular connective tissue***,* composed of dense, irregular connective tissue with abundant adipose tissue, separates lobules. This tissue is sparsely cellular, containing mostly fibroblasts and adipocytes.

2. **Intralobular connective tissue** is composed of loose connective tissue and lies within lobules and surrounds ducts and alveoli (parenchyma) of the gland. This connective tissue is highly cellular, containing many plasma cells, lymphocytes, and macrophages, as well as fibroblasts

B. **Parenchyma***.* Functional components of the breast

1. **Ducts***.* Form the majority of an inactive gland and are always present. Consist of an epithelial lining, which can be secretory, and **myoepithelial cells***.* Development of the ducts is regulated by estrogen.

2. **Alveoli***.* Derived from outgrowths of the ducts and are only present during later stages of pregnancy and lactation. Alveoli consist of alveolar cells and myoepithelial cells. **Alveolar cells** are the major cells responsible for the synthesis and secretion of milk, and their development is regulated by progesterone.

III. Functional stages of the breast

A. **Prepuberty***.* Composed entirely of the duct system; no secretory alveolar units are present. At this stage, the breast in the male and female are similar

B. **Puberty (female)**

1. Enlargement of the breast is due primarily to the accumulation of adipose tissue.

2. Rising estrogen levels at this time stimulates the growth and branching of the duct system.

3. No secretory alveoli are present.

C. **Inactive (non-pregnant)**. Minor alveolar development with a slight amount of secretory activity and fluid accumulation may occur during mid to late phases of the menstrual cycle.

D. **Pregnancy**

1. Early to mid-pregnancy

    a. Prominent increase in duct branching induced by estrogen; development of alveoli as evaginations from those ducts is induced by progesterone.

    b. Interlobular connective tissue becomes more cellular with increased numbers of plasma cells, polymorphonuclear leukocytes, and lymphocytes.

2. Late pregnancy

    a. Significant breast enlargement due to hypertrophy of alveolar cells

    b. Lumens of ducts and alveoli widen as secretory products accumulate

E. **Lactation**

1. Alveolar cells secrete by both merocrine and apocrine modes of secretion.

    a. **Apocrine**. Lipid secretion; lipid droplets coalesce in the apical cytoplasm and are released along with some membrane and surrounding cytoplasm

    b. **Merocrine**. Protein secretion; protein, packaged in membrane-bound, secretory vesicles in the Golgi, are released by exocytosis.

2. Two types of secretory products

    a. **Colostrum**. Secreted for the first few days after birth; protein rich with a high antibody content.

    b. **Milk**. Secretory product released after the colostrum phase; milk has a high lipid content compared with colostrum and also contains protein, carbohydrates, and antibodies.

3. Secretion and ejection of milk is maintained by a **neurohormonal reflex arc**. Infant suckling stimulates sensory nerves, whose activity results in prolactin release from the pituitary gland to maintain milk synthesis and secretion. Similarly, suckling causes oxytocin release, which stimulates the ejection of milk due to contraction of myoepithelial cells.

4. Cessation of suckling results in decreased secretory activity, degeneration

of alveoli, and the end of lactation.

Exocrine glands -- Exocrine secretory cells remain either within or attached to the epithelial surface from which they originate. Secretory cells release their product(s) onto that surface epithelium directly or indirectly via ducts. Units of secretory cells are organized into tubules (test-tube shaped) or grapefruit-shaped acini (sing. acinus). Acini may also be called alveoli (sing. alveolus).

1 of 6

A unicellular gland, the simplest exocrine gland, is a single secretory cell that remains in the epithelium where it forms. Although other examples exist, the most common unicellular exocrine gland is the goblet cell, demonstrated here. Goblet cells secrete mucus to lubricate the surface epithelium.

- Acinar >
- Tubuloacinar >

1 of 6

The least complex of the simple tubular glands consists of a secretory unit shaped like a test tube that connects directly to the surface epithelium without an intervening duct. Mucus is a common product of tubular secretory units, so cells of tubular glands frequently appear pale and frothy. Intestinal glands in small and large intestine are simple tubular glands.

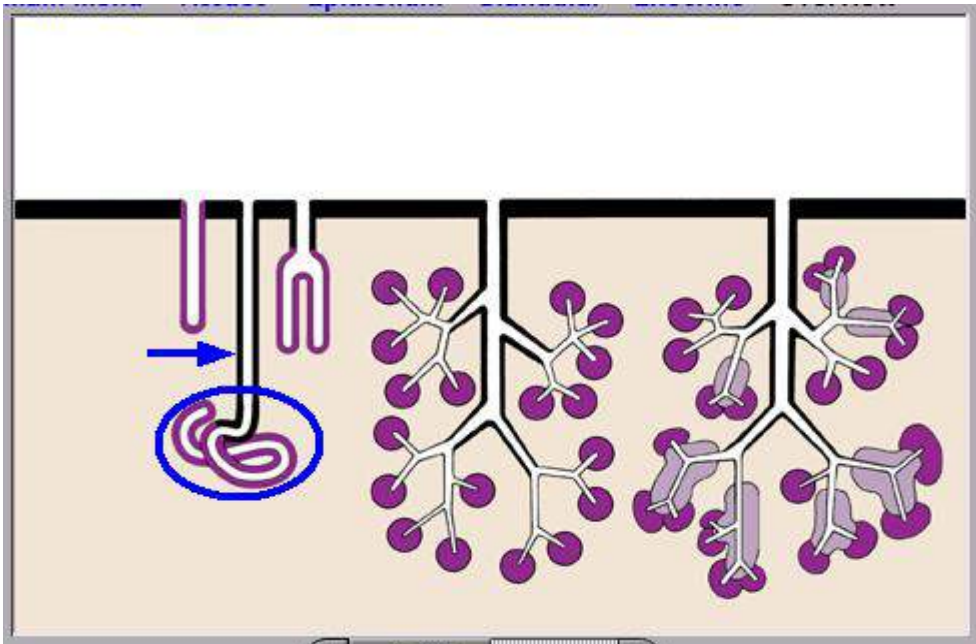
1 of 6

A sheet gland is a little more complex than a unicellular gland in that all cells of a surface epithelium differentiate into secretory cells, forming a secretory sheet. The only sheet gland in the human lines the lumen of the stomach, where the mucus it secretes protects the stomach from gastric acids.



1 of 6

A simple coiled tubular gland has a tubular secretory unit (blue oval) that coils on itself like a ball of yarn; secretory product is conveyed to the surface epithelium by a single duct (blue arrow). The most common simple coiled tubular gland in the human does not secrete mucus, but is specialized to produce sweat.

1 of 6

In simple branched tubular glands, secretory tubules (red arrow) branch; if a duct (green arrow) is present, it does not branch. (If the duct branched, this would be a compound gland.) Gastric glands are simple branched tubular glands.

Compound glands are large, often macroscopic structures with branching ducts. Secretory units may be entirely acinar, entirely tubular or a combination of acinar and tubular. Compound glands can be subdivided into smaller subunits called lobules, each consisting of a duct and its attached secretory units.

1 of 6

Compound acinar glands have branching ducts (blue arrows), lobules (oval) and acinar (alveolar) secretory units (magenta spheres). An acinus usually secretes a serous product and resembles a grapefruit; when sectioned, secretory cells resemble grapefruit wedges. Each acinus has a small central lumen (green arrows), sufficient to transport its watery product.

Sheet gland
Simple branched tubular gland – This image of the stomach shows the structure of a simple, branched tubular gland. The secretory sheet lining the surface invaginates to form a gastric pit that acts as a duct for the gland. The secretory portions of the gland branch at their junction with the gastric pit. 40x

Surface epithelia – Surface epithelia, covering the body exterior and lining all interior surfaces, are classified by the shape of the cells immediately facing the lumen or surface and by the number of cell layers composing the epithelium. All epithelia show polarity, are avascular, and rest on a basement membrane that they produce with the underlying connective tissue.

Simple epithelia consist of a single layer of cells resting on a basement membrane (arrows). The cells may be squamous shaped (like a fried egg), cuboidal, or columnar. Simple epithelia may have surface modifications such as microvilli and cilia.

1 of 1
Simple squamous epithelium consists of a single layer of flattened cells with a very thin cytoplasm, resembling the white of a fried egg; the nucleus of the squamous cell, bulging into the lumen, is analogous to the egg yolk. Because of its thinness, simple squamous epithelium lines structures across which rapid transport is required, such as capillaries and lung alveoli.

1 of 1
Simple columnar epithelium is composed of a single layer of columnar-shaped cells. The oval nuclei in this epithelium are usually located in the basal half to the center of each cell. Simple columnar epithelium may possess microvilli, such as in the small intestine where they aid in absorption of digested food, or cilia, such as in the oviduct where they transport germ cells.

Stratified epithelia are composed of two or more cell layers and are classified by the shape of the surface layer of cells. Stratified epithelia are not involved with transport or absorption but provide a protective layer to the underlying tissues.

1 of 1
Stratified squamous moist (or nonkeratinized) epithelium consists of multiple layers; cells in the uppermost layer are living and squamous in shape. This epithelium is designated "moist," because it usually has glands that lubricate and moisturize its surface. This epithelium lines any interior body surface that requires strong protection, such as the esophagus and vagina.

1 of 1
Stratified squamous dry (or keratinized) epithelium is composed of multiple layers; cells forming this tissue flatten as they approach the surface. These epithelial cells produce a cornified layer at the surface that is composed of flattened, non-nucleated, dead cells filled with keratin (arrow). Stratified squamous keratinized epithelium is part of skin.

1 of 1

Stratified columnar epithelium is composed of multiple layers, the uppermost of which is columnar-shaped. This epithelium is not found in a definitive location but is frequently seen in areas of epithelial transition, for example, in ducts as their linings are modified from a simple epithelium to a stratified squamous epithelium onto which the gland would secrete.

1 of 1

Transitional epithelium is also classified as stratified cuboidal, because its surface cells frequently assume a cuboidal shape. Transitional epithelium lines urinary passages that distend. Surface cells are called dome cells (arrow), because of their bulging shape; these cells, however, flatten to a squamous shape when the epithelium is distended, thus the name transitional.

1 of 1
All epithelia rest on a basement membrane, which consists of a basal lamina, produced by the epithelial cells, and a reticular lamina, produced by fibroblasts in the underlying connective tissue. Because the basal lamina and reticular lamina cannot be resolved with the light microscope, the term basement membrane is used in light microscopy to refer to both of these structures, collectively.

Pseudostratified columnar epithelium -- Pseudostratified epithelium has tall columnar and short basal cells, all of which contact the basement membrane. The layered appearance of the nuclei make this epithelium appear stratified, hence the term, pseudostratified. Because this is truly a simple epithelium, it can possess associated structures, such as stereocilia. Epididymis 1000x

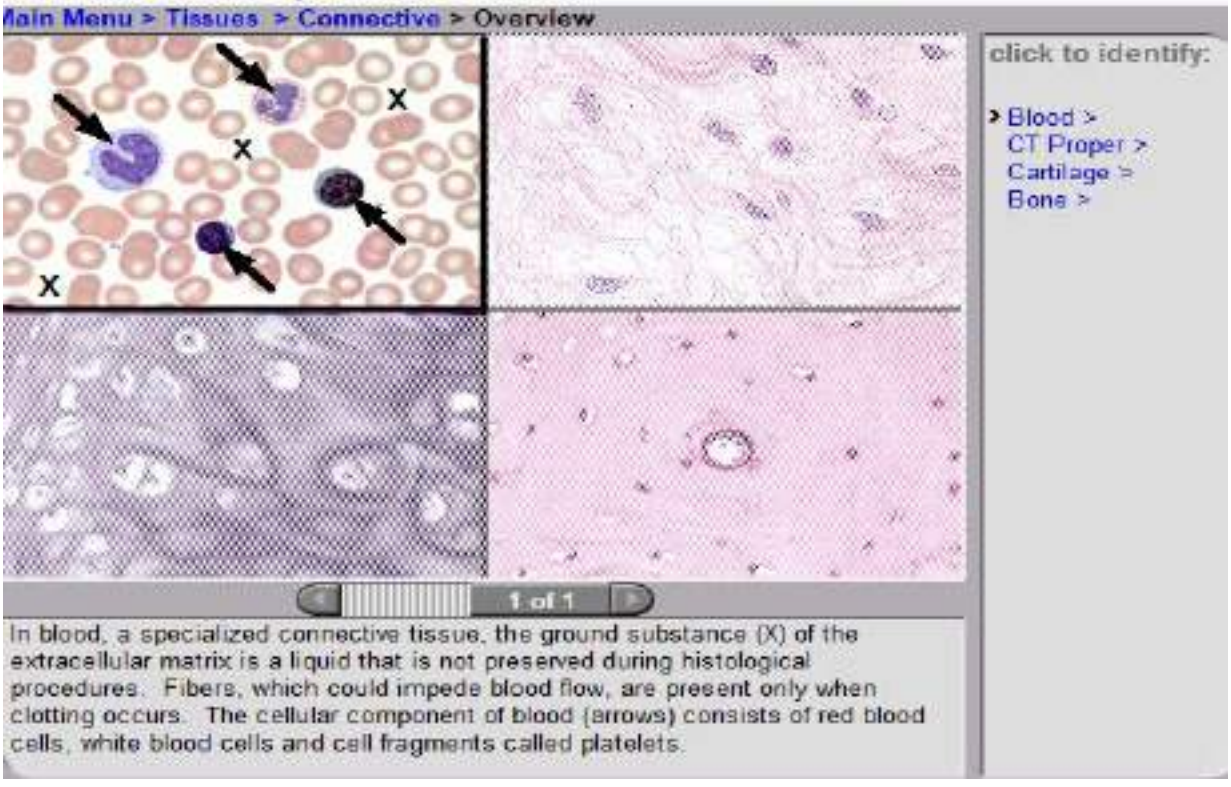
Connective tissue (CT) is characterized by an abundant extracellular matrix surrounding cells. The matrix is composed of fibers, ground substance and tissue fluid. Variation in type, consistency and quantity of these components, in addition to variation in cell type and numbers, imparts characteristics and functions unique to each of the four major connective tissue subdivisions.



In blood, a specialized connective tissue, the ground substance (X) of the extracellular matrix is a liquid that is not preserved during histological procedures. Fibers, which could impede blood flow, are present only when clotting occurs. The cellular component of blood (arrows) consists of red blood cells, white blood cells and cell fragments called platelets.

1 of 1
In CT proper the ground substance (blue arrows) is a gel, providing padding qualities to the tissue. Fibers (red arrows), such as collagen, elastic and reticular, provide strength and elasticity. Numerous cells (black arrows) include fibroblasts producing extracellular matrix, white blood cells involved in the immune response, and macrophages, mast cells and adipocytes.

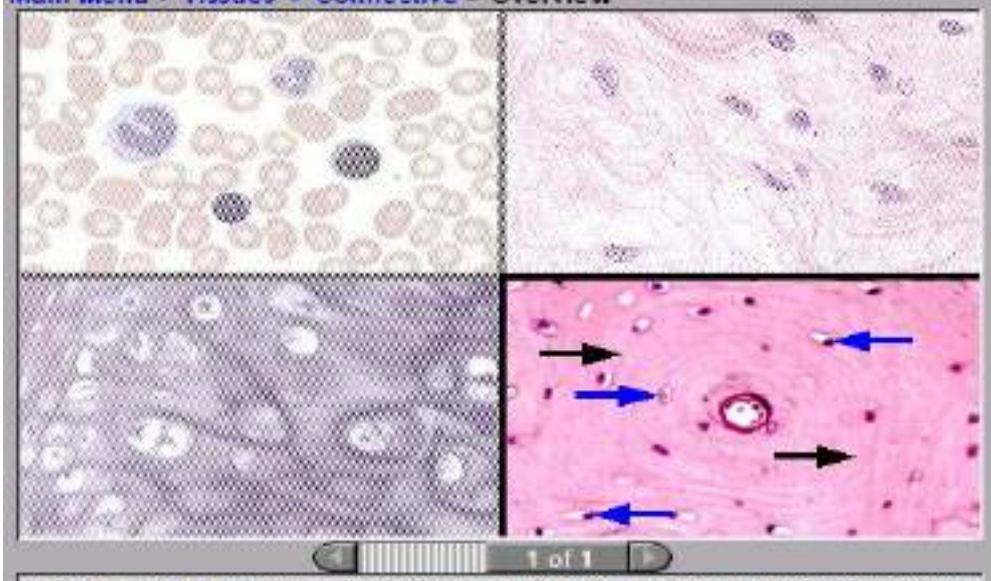
In cartilage the ground substance (blue arrow) is a flexible solid, providing deformable support. Fibers (yellow arrow) vary with cartilage type. Cartilage cells (black arrows) are called chondroblasts when they lie on the surface of cartilage and chondrocytes, when they are embedded in the cartilage matrix. Both cell types produce cartilage matrix.

Main Menu > Tissues > Connective > Overview



1 of 1

In bone, ground substance is similar to cartilage but is impregnated with calcium phosphate to provide rigidity; collagen is the primary fiber type. This extracellular matrix is indicated by black arrows. Three cell types are present in bone: osteoblasts lie on bone surfaces and produce matrix; osteocytes (blue arrows) are osteoblasts entombed in matrix; osteoclasts break down bone.

Macrophage and mast cell -- A mast cell is a motile cell that is easily identified by its centrally located, heterochromatic, spherical nucleus and its coarse red granules containing histamine and heparin. A macrophage, with its indented nucleus, has readily visible cytoplasm. A lymphocyte and an active fibroblast can also be seen. 1000x

CHAPTER 14

LYMPHOID SYSTEM

GENERAL CONCEPTS

I. Functions

A. Provides immune surveillance and defense against foreign substances and microorganisms

B. Provides immune tolerance, distinguishing between "self" and "non-self"

C. Absorbs lipids into small lymphoid vessels (lacteals) in intestinal villi for distribution to the blood stream and liver

D. Helps to maintain fluid balance by accumulating tissue fluid and white blood cells in lymph vessels and returning them to the blood

II. Overview of lymphoid components

A. **Primary lymphoid organs and structures**

1. **Bone marrow**. Site of origin of T and B lymphocytes. B lymphocytes directly seed secondary lymphoid structures and organs.

2. **Thymus**. T lymphocytes from bone marrow undergo further maturation in the thymus before seeding secondary lymphoid structures and organs.

B. **Secondary lymphoid organs and structures** (from least to most complex)

1. **Diffuse lymphoid tissue**

2. **Lymphoid nodules**. Both solitary and in aggregates.

3. **Tonsils**

4. **Lymph nodes**

5. **Spleen**

C. Major lymphoid cell types

1. **B lymphocytes** originate and mature in the bone marrow, then seed secondary lymphoid structures and organs. B cells differentiate into B memory cells and plasma cells, providing humoral immunity.

2. **T lymphocytes** originate in bone marrow, mature in the thymus, and subsequently seed secondary lymphoid tissue. T cells differentiate into helper, memory, and cytotoxic cells. T lymphocytes provide cell-mediated immunity and assist B lymphocytes in their humoral response.

3. **Plasma cells** differentiate from B lymphocytes and produce humoral antibodies.

4. **Macrophages** and **dendritic cells** phagocytose foreign matter, enhance the body's response to antigen by "presenting" antigen to lymphocytes, and secrete immunomodulatory factors.

D. **Lymph vessels *(images)***

1. Are thin-walled vessels lined with endothelium

2. Begin as blind-ended lymphatic capillaries in tissues. These capillaries accumulate tissue fluid, which is called lymph once it is enclosed by the capillary.

3. Gradually increase in diameter and have valves located within their walls. Lymph nodes are positioned along these vessels.

4. Unite to form two **lymph ducts** (thoracic and lymphatic ducts) that return lymph to the venous side of the blood vasculature system

E. **High endothelial venules (HEVs) *(images)***

1. Located in appendix, tonsils, Peyer's patches, and especially in lymph nodes, but not in spleen

2. Endothelium lining these venules is simple cuboidal rather than simple squamous epithelium

3. Allow transport of lymphocytes through the endothelium, thus permitting diapedesis of these cells and the dissemination of immunological information between different regions of the body

F. Stroma of lymphoid structures and organs

1. **Reticular cells** produce reticular fibers and act as fixed macrophages as they ensheathe these fibers. Reticular cells and reticular fibers together constitutes reticular connective tissue.

2. **Reticular fibers** are composed of collagen type III and form a meshwork that allows fluid to percolate through it while providing delicate, nondistensible support for cells suspended within it.

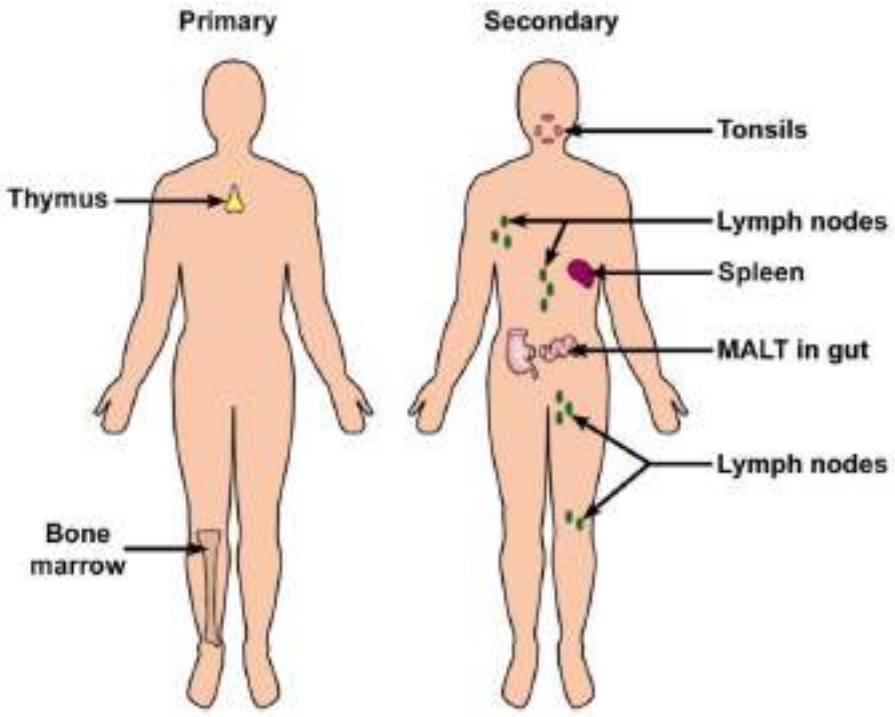

FIGURE 14.1. The primary and secondary lymphoid structures and organs. MALT, mucosal-associated lymphoid tissue.

COMPONENTS OF THE LYMPHOID SYSTEM

I. **Diffuse lymphatic tissue *(images)***

A. Located in lamina propria of any organ system opening to the exterior of the body, such as respiratory and digestive systems, where an antigen could penetrate the epithelium and enter the lamina propria. Diffuse lymphoid tissue in the lamina propria is part of the **mucosal-associated lymphoid tissue (MALT)**. Diffuse lymphatic tissue is also located in tonsils, lymph nodes, and spleen.

B. Composed of an unorganized cluster of lymphocytes and other cells capable of responding to an antigen that reaches it.

C. Filters and provides immune surveillance for tissue fluid of the lamina propria in which it is located

II. **Lymphoid nodules *(images)***

A. Distribution

1. Lamina propria of any organ opening to the exterior of the body. May occur singly (solitary) or in clusters (aggregates) such as in tonsils and

Peyer's patches in the small intestine. Lymphoid nodules in the lamina propria are part of MALT.

2. Lymph node and spleen

B. Structure

1. **Primary nodule**. The nodule present before antigen stimulation. The spherical nodule consists primarily of densely packed B lymphocytes.

2. **Secondary nodule**. After antigen stimulation, a central pale core, the **germinal center**, appears. This center is composed of immunoblasts that divide to form lymphocytes that accumulate in the densely packed, peripheral zone of the nodule.

C. Function

1. Filter and provide immune surveillance for the fluid of the layer/organ in which it is located: tissue fluid in the lamina propria, lymph in lymph nodes, and blood in the spleen.

2. Detect specific antigens and causes proliferation of antigen-specific B lymphocytes

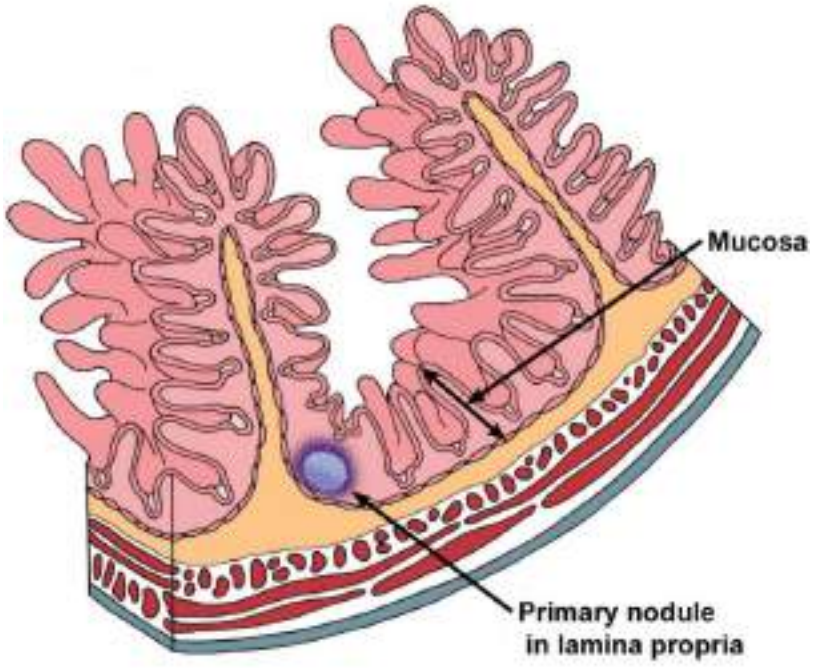

FIGURE 14.2. Nodular lymphoid tissue in the mucosa is part of MALT, mucosal associated lymphoid tissue. Longitudinal section of the small intestine.

III. **Tonsils *(images)***

A. **Pharyngeal**, **lingual**, and **palatine tonsils** are located at the junction of the oral cavity with the oral pharynx and in the nasopharynx.

B. Located in the lamina propria of the mucosa

C. Structure

1. Aggregations of lymphoid nodules and diffuse lymphoid tissue

2. **Crypts** or folds of surface epithelium invade the tonsils.

3. Partially encapsulated by connective tissue separating it from underlying tissues

D. Filter and provide immune surveillance for the tissue fluid of the lamina propria in which they are locate

IV. **Lymph nodes *(images)***

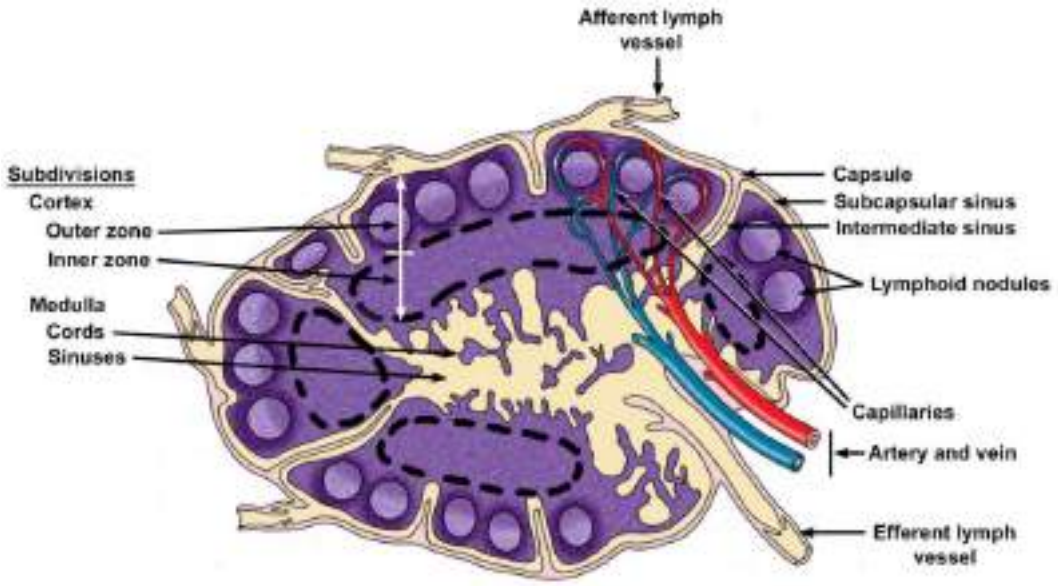

FIGURE 14.3. Lymph node.

A. Small, encapsulated, kidney-shaped organs occurring in chains or groups along lymph vessels

B. Structure

1. **Cortex**

a. **Capsule** of dense connective tissue surrounds the node and sends short trabeculae into the node. Reticular connective tissue forms the stroma for the remainder (interior) of the node.

b. **Outer zone**. Filled primarily with lymphoid nodules composed of B lymphocytes

c. **Inner zone (paracortex or deep cortex)**. Filled with diffuse lymphoid tissue composed of T lymphocytes

d. **Sinuses** in cortex. Loose network of macrophages and reticular fibers through which lymph percolates

i. **Subcapsular sinus** lies immediately beneath the capsule and receives incoming lymph fluid from afferent lymphatic vessels that enter through the capsule.

ii. **Intermediate sinuses**. Lie adjacent to the trabeculae. Receive lymph from the subcapsular sinus and continue as medullary sinuses

2. **Medulla**. Composed of:

a. **Medullary cords** of B lymphocytes that extend from the inner cortex into the medulla

b. **Medullary sinuses**. Continuations of the intermediate sinuses in the cortex. Lymph flows from medullary sinuses into the efferent lymph vessels that exit at the hilum of the node.

C. Blood supply. Small arteries enter at the hilum to supply a capillary plexus in the outer cortex. The capillaries anastomose to form HEVs in the paracortex and small veins that exit at the hilum.

D. Filter and provide immune surveillance for lymph

V. **Spleen *(images)***

A. Encapsulated, intraperitoneal organ located in upper left quadrant of the abdominal cavity

B. Structure

1. **Capsule** surrounds organ, sending trabeculae into the spleen. Larger blood vessels traverse the trabeculae.

2. Subdivisions

a. **White pulp** appears white in fresh specimens and is composed of:

i. **Periarterial lymphoid sheath (PALS)**. A sleeve of T lymphocytes that surrounds a central arteriole as soon as it exits from a trabecula

ii. **Lymphoid nodules**, composed of B lymphocytes, are randomly located along and embedded in the PALS.

b. **Red pulp** appears red in fresh specimens because of the abundant venous sinuses it possesses.

i. **Splenic cords (of Billroth)**. Cords of lymphocytes (T and B), macrophages, plasma cells, and other lymphoid cells suspended in a reticular connective tissue stroma. Surrounded by:

ii. **Splenic sinuses**. Venous sinuses separating splenic cords. These sinuses are lined by endothelial cells and surrounded by reticular fibers.

3. The spleen filters and provides immune surveillance for the blood percolating through it. The spleen also phagocytoses aged and abnormal erythrocytes and stores blood.

C. Blood flow through the spleen

1. **Splenic artery** enters at the hilum of the spleen and branches into arteries that lie in the trabeculae.

2. Arteries exit from the trabeculae as **central arterioles** and are immediately surrounded by the PALS. The central arteriole becomes eccentrically located when it is displaced by a lymphoid nodule. Branches from the central arterioles supply the PALS, including forming marginal sinuses at the perimeter of the white pulp.

3. Central arterioles lose their PALS ensheathment and form a series of smaller arterioles in the red pulp. These arterioles either:

a. Open directly into a splenic sinus **(closed circulation)**

b. Open into a splenic cord where the blood percolates through the cells of the cord before entering a splenic sinus **(open circulation)**

4. **Trabecular veins** are formed by splenic sinuses anastomosing and then entering a trabecula. Trabecular veins anastomose to form the splenic vein.

5. The **splenic vein** exits at the hilum of the spleen.

VI. **Thymus** ***(images)***

A. The thymus is a primary lymphoid organ that receives immature lymphocytes (thymocytes) from the bone marrow. These cells mature in the thymus and are carried to secondary lymphoid structures/organs via the blood vascular system.

B. The thymus is located in the superior mediastinum under the sternum. The thymus involutes with age.

C. Structure

1. A connective tissue **capsule** surrounds the thymus and extends into the thymus, dividing it into lobules.

2. The **stroma** is formed by a network of reticular cells of endodermal, rather than the usual mesodermal, origin and are called, therefore, **epithelial reticular cells**. These cells do not form fibers.

3. Each lobule contains an:

   a. Outer **cortex** that is densely packed with thymocytes, the developing T lymphocytes. These cells mature in the cortex, then migrate into the medulla where they enter the blood stream for transport to secondary lymphoid structures and organs.

   b. Inner **medulla** has fewer thymocytes and, therefore, stains more palely than does the cortex. **Hassall's corpuscles** are the degenerating remains of the epithelial reticular cells with their keratin granules and are diagnostic for the thymus.

D. A blood-thymic barrier is formed around capillaries in the cortex, so that the developing lymphocytes are not exposed to circulating antigens.

CHAPTER 17

MALE REPRODUCTIVE SYSTEM

GENERAL CONCEPTS

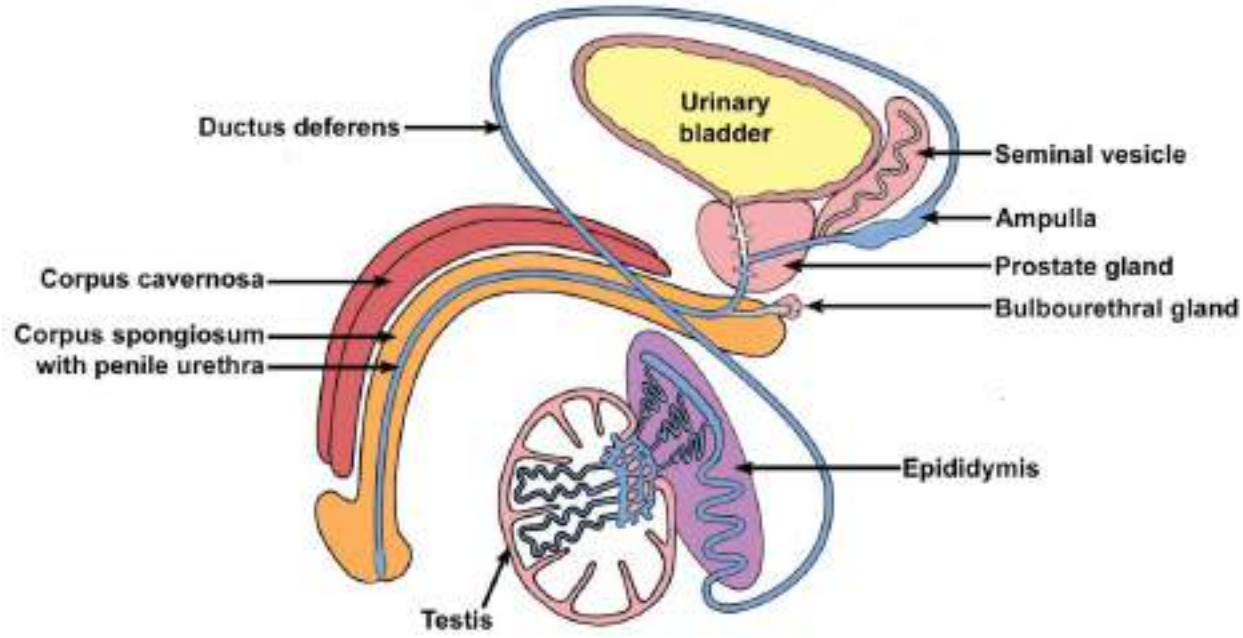

FIGURE 17.1. Components of the male reproductive system

I. Components

A. Testis. Paired organs

1. Seminiferous tubules
2. Rete testis (intratesticular ducts)

B. Genital ducts

1. Epididymis. Paired organs, each containing the duct of the epididymis
2. Ductus deferens. Paired ducts
3. Ejaculatory duct. Paired ducts
4. Urethra

C. Major genital glands

1. Seminal vesicles. Paired glands
2. Prostate. Single gland
3. Bulbourethral glands. Paired glands

II. Functions

A. Produce sperm

B. Produce male sex hormones

C. Produce seminal fluid

D. Propel sperm and seminal fluid (semen) to exterior

TESTIS

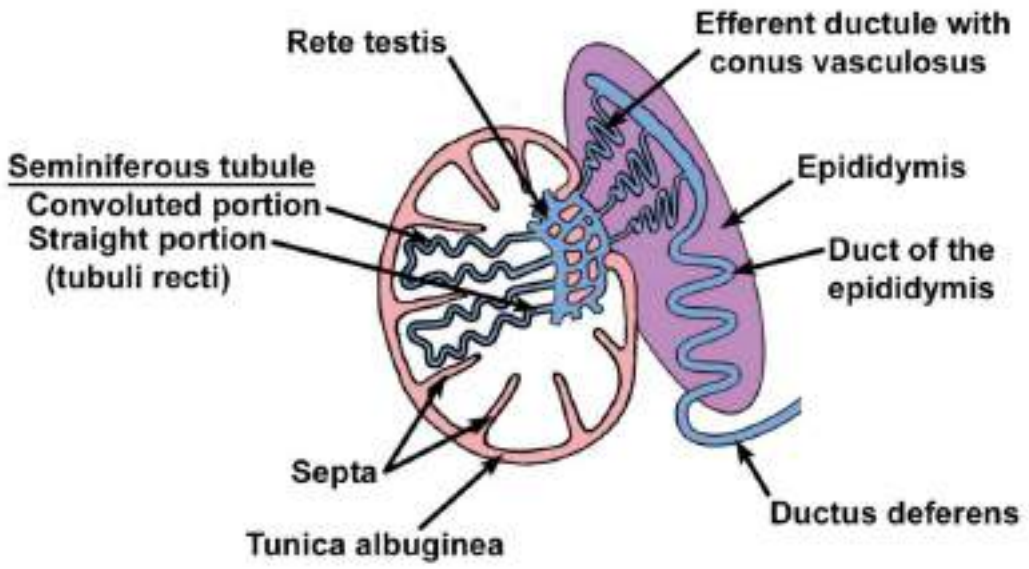

FIGURE 17.2. Components of the testis

GENERAL ORGANIZATION

I. Paired, ovoid organs; serve both exocrine (sperm production) and endocrine (testosterone production) functions; suspended in the scrotum

II. Coverings and connective tissue framework (external to internal): ***(images)***

A. **Tunica vaginalis**. A serosa (peritoneum) that accompanied the testis

embryologically in its retroperitoneal descent from the abdomen to the scrotum. Covers the anterior and lateral surfaces of the testes but not their posterior surfaces.

B. **Tunica albuginea**. A layer of dense connective tissue beneath the tunica vaginalis, encapsulating the testis.

C. **Mediastinum** of the testis

1. Thickening of tunica albuginea, projecting into the testis from its posterior surface

2. Seminiferous tubules converge at the mediastinum where they join the rete testis.

3. **Rete testis**. Interconnecting channels in the mediastinum that receive the contents of the seminiferous tubules

D. **Septa**, connective tissue partitions extending from the mediastinum toward the tunica albuginea, separate each testis into about 250 lobules. (Note: For clarity, Figure 17.2 shows the septa originating from the tunica albuginea rather than from mediastinum)

III. Internal structure of testis ***(images)***

A. Consists of lobules that are pyramidal in shape with their apices directed toward the mediastinum and their bases adjacent to the tunica albuginea

B. Composition of lobules

1. **Stroma**. Loose connective tissue, many blood vessels and lymphatics

2. Parenchyma

a. **Seminiferous tubules, convoluted portions**

i. One to four loop-shaped, tortuous tubules per lobule with both ends opening at the mediastinum

ii. Composed of seminiferous epithelium where spermatozoa production occurs

iii. Surrounded by a **tunica propria**, a connective tissue layer located beneath the basal lamina of the seminiferous epithelium. Myoid cells, possessing contractile properties, are located in this layer.

b. **Seminiferous tubules, straight portions (tubuli recti)** are

located at the periphery of the mediastinum. Interconnect the convoluted portions of the seminiferous tubule with the rete testis in the mediastinum

c. **Interstitial cells (of Leydig)**. Clusters of endocrine-secreting cells lie outside the seminiferous tubules within the CT stroma; produce testosterone

MICROSCOPIC APPEARANCE OF THE PARENCHYMA OF THE TESTIS

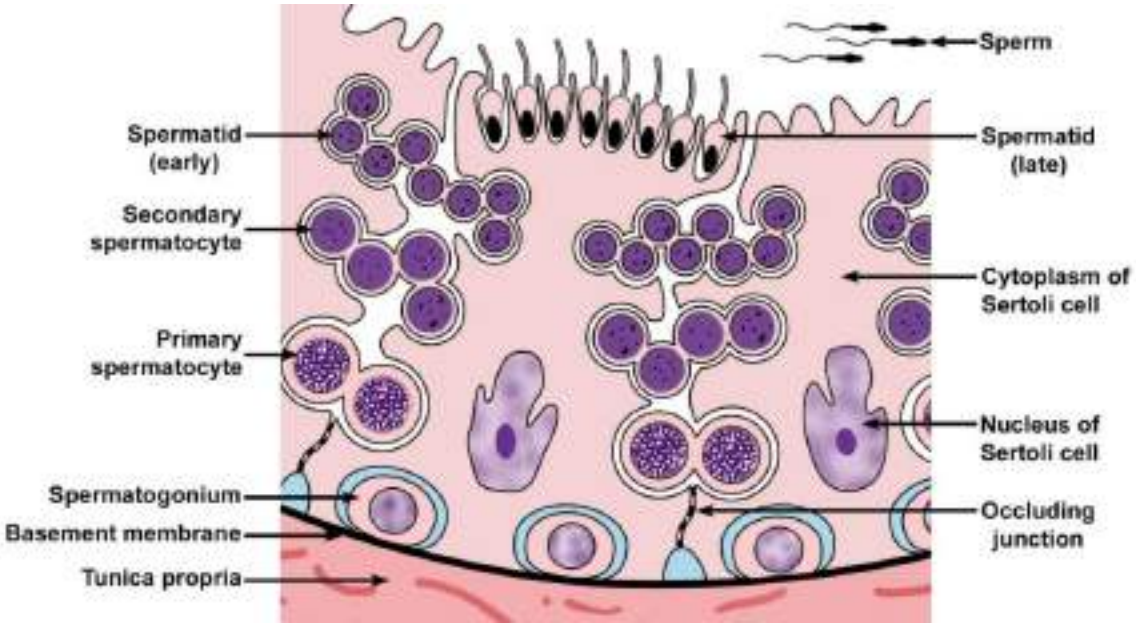

FIGURE 17.3. Seminiferous epithelium in the convoluted portion of seminiferous tubule.

I. **Interstitial cells (of Leydig)**. (endocrine portion).

A. Arranged as clusters of cells in the stroma between seminiferous tubules

B. Cytology

1. Euchromatic nucleus

2. Eosinophilic cytoplasm possesses cytological features of steroid-producing cells, such as extensive SER, large numbers of lipid droplets and mitochondria with tubular cristae.

C. Function. Secrete testosterone under the influence of luteinizing hormone (LH).

II. Exocrine portion. **Seminiferous epithelium** lining the convoluted portions of

the seminiferous tubules (exocrine function).

A. **Supporting cells of Sertoli**

1. Tall, columnar cells that rest on the basal lamina and extend to the lumen

2. Nucleus is euchromatic, ovoid, and infolded; its long axis usually lies perpendicular to, but not immediately adjacent to, the basal lamina.

3. Numerous lateral processes surround and invest the maturing germ cells. The most basal of these processes forms a series of tight (occluding) junctions with similar processes of adjacent Sertoli cells.

4. **Blood-testis barrier** is formed by tight (occluding) junctions that unite the basal processes of adjacent Sertoli cells forming a:

    a. **Basal compartment** with access to blood-borne materials and which contains spermatogonia and earliest primary spermatocytes

    b. **Luminal compartment**

        i. Provides a unique microenvironment for developing germ cells that protects these cells from immunologic attack and concentrates hormones needed for sperm production

        ii. Contains later primary spermatocytes, secondary spermatocytes, and spermatids

5. Functions

    a. Mediate exchange of nutrients to germ cells

    b. Form blood-testis barrier to protect developing germ cells from immunologic attack

    c. Break down excess spermatid cytoplasm

    d. Produce testicular fluid

    e. Secrete **androgen-binding protein** that binds to and concentrates testosterone in the seminiferous epithelium

    f. Produce **inhibin**, which inhibits the secretion of follicle stimulating hormone (FSH) from the adenohypophysis

    g. Orchestrate movement of germ cells through semininferous epithelium and facilitate cytodifferentiation and subsequent release of spermatozoa into the lumen of the seminiferous tubule

B. Germ cells (spermatogenic cells)

1. Form a stratified seminiferous epithelium

2. Cell types

   a. **Spermatogonia**

      i. Are diploid cells resting on the basal lamina

      ii. Are of two varieties. **Type A spermatogonia** divide mitotically to perpetuate self and to form type B cells. **Type B spermatogonia** divide mitotically to form primary spermatocytes.

      iii. Undergo incomplete cytokinesis so resulting cells remain attached to each other during spermatogenesis

      iv. Divide mitotically to produce primary spermatocytes

   b. **Primary spermatocytes**

      i. Are the largest germ cells; each nucleus is 1.5 times larger than that of a spermatogonium

      ii. Form in the basal compartment, then probably migrate through the tight junctions between Sertoli cell processes forming the blood-testis barrier to the luminal compartment

      iii. Remain in prophase about one-third of the spermatogenic cycle, so many are seen. Nuclei contain highly condensed chromosomes.

      iv. Are diploid cells that complete meiosis I (reductional division) to form secondary spermatocytes

   c. **Secondary spermatocytes**

      i. Are haploid cells whose pale staining nuclei are similar in size to those of the spermatogonia nuclei

      ii. Are present for only eight hours of the entire 64-day spermatogenic cycle; therefore, very few are seen.

      iii. Divide by meiosis II (equational division) to form spermatids

   d. **Spermatids**

      i. Are haploid cells whose nuclei are initially about two-thirds the size

of spermatogonia nuclei

ii. Are located near the lumen of the seminiferous tubules

iii. Do not divide but undergo cytodifferentiation **(spermiogenesis)** to form spermatozoa

(a) Intercellular bridges break down.

(b) Nucleus condenses and elongates.

(c) Acrosome forms. An acrosome is a modified lysosome containing enzymes to aid the sperm in penetrating the zona pellucida surrounding the secondary oocyte.

(d) Flagellum forms.

(e) Excess cytoplasm is shed.

e. **Spermatozoa**

i. Are haploid cells

ii. Are anatomically mature, but incapable of fertilization at this time

iii. Are released from Sertoli cells into the lumen of the seminiferous tubules **(spermiation)**

SPERMATOGENESIS

I. **Spermatogenesis** is a multi-staged process by which diploid somatic cells (spermatogonia) in the basal compartment become haploid spermatozoa lying free in the lumen of the seminiferous tubules.

II. Stages

A. **Spermatocytogenesis**. At puberty, spermatotogonia (2N cells) differentiate in the testis and divide by mitosis either to perpetuate their own cell line or produce primary spermatocytes that begin meiosis; cytokinesis is incomplete

B. Meiosis. Two cell divisions convert diploid primary spermatocytes to haploid (i.e., reduction of chromosomes and DNA by half); cytokinesis is incomplete.

1. **Meiosis I**. Primary spermatocytes (diploid) form secondary spermatocytes (haploid).

2. **Meiosis II**. Secondary spermatocytes form spermatids (haploid).

C. **Spermiogenesis**. Cytodifferentiation of spermatids (haploid) into spermatozoa (haploid); no cell division occurs during this stage.

D. **Spermiation**. Release of mature sperm into lumen of seminiferous tubule

III. Under control of follicle stimulating hormone (FSH) from the anterior pituitary

IV. One cycle lasts about 64 days, with a new cycle beginning in any given location about every 16 days.

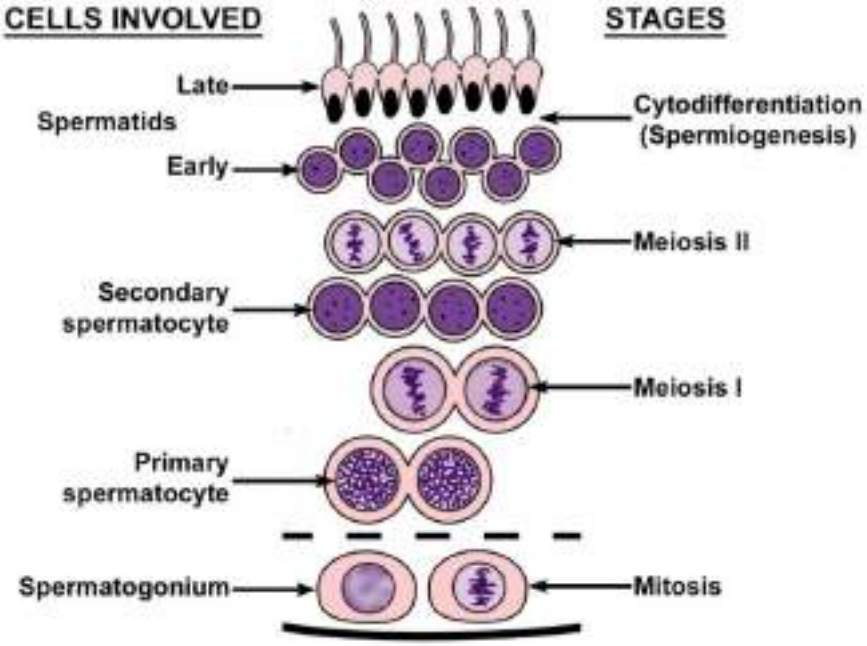

FIGURE 17.4. The stages and cells of spermatogenesis

COMPARISON OF OOGENESIS WITH SPERMATOGENESIS *(image)*

I. Gametogenesis, the formation of haploid (1N) ova and sperm, is a multistaged process that includes both mitosis and meiosis. While chromosomal events producing sperm (spermatogenesis) and ova (oogenesis) are similar, cytoplasmic stages, the timing of divisions and the number of gametes formed is different between the male and the female.

II. Stages

A. Mitosis

1. Beginning at puberty in males, diploid precursor spermatogonial cells divide to form diploid spermatogonia. Spermatogonia, in turn, divide by mitosis, renewing their own cell line, as well as producing cells that enter

meiosis. In contrast in the female, before birth diploid precursor oogonial cells divide to form diploid oogonia. Oogonia divide mitotically, again before birth, forming only cells that enter meiosis, thus depleting their own cell line. Oogonia are not self-renewing and, at birth, no oogonia remain in the ovary.

2. In males, cytokinesis of spermatogonia and primary and secondary spermatocytes is incomplete, and thus, cells remain attached to each other. In females, cytokinesis is complete.

B. Meiosis. In the male, primary and secondary spermatocytes complete both meiotic stages, producing four functional, haploid spermatozoa of equal size from each diploid spermatogonia. In contrast, in the female, when primary and secondary oocytes complete meiosis, only a single, functional, haploid ovum is formed, along with two or three small, nonfunctional satellite cells (polar bodies).

C. Maturation

1. In males, after the completion of meiosis, spermatids undergo morphological changes, transforming themselves from spherical cells to tadpole-shaped spermatozoa, and breaking their cytoplasmic connections. No such maturation process occurs in the female.

2. In females, the completion of meiosis II, with the formation of an ovum, occurs only after fertilization. If fertilization does not occur, the secondary oocyte is destroyed or degenerates.

3. Fusion of the haploid male and female nuclei produces a diploid zygote, reconstituting the full complement of chromosomes.

III. Spermatogenesis occurs throughout the reproductive life of a male, producing millions of sperm during this span. Oogenesis lasts for only 30-40 years in the female and produces only a minimal number of ova, because completion of oogenesis is dependent on fertilization.

COURSE OF SPERM WITHIN THE TESTIS *(images)*

I. **Seminiferous tubules, convoluted portion**. Seminiferous epithelium where sperm production occurs; sperm are released into the lumen of this portion of the tubule from Sertoli cells.

II. **Seminiferous tubules, straight portion (tubuli recti)**

A. Lined by simple columnar epithelium whose cells resemble Sertoli cells

B. Connects convoluted portion of seminiferous tubules with rete testis

III. **Rete testis (intratesticular ducts)**

A. Is a meshwork of channels within mediastinum of testis

B. Lined by simple cuboidal cells, many of which possess a single flagellum

C. Connects the straight portion of the seminiferous tubules with efferent ducts in the epididymis

GENITAL DUCTS EXTERNAL TO THE TESTIS

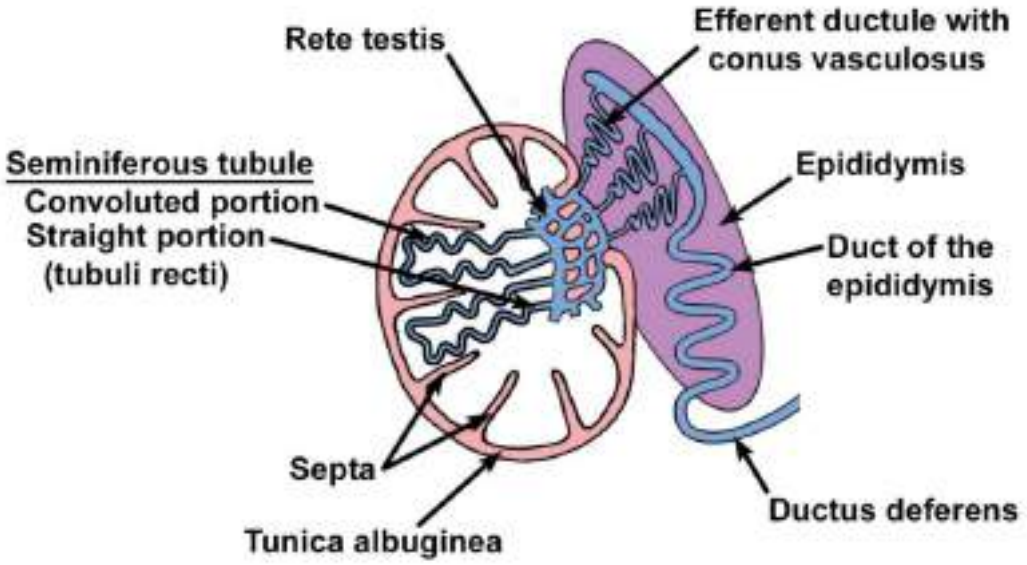

FIGURE 17.3. Components of the testis and epididymis

EPIDIDYMIS *(images)*

I. The epididymis is a comma-shaped organ lying posterior to the testis that is divided into head, body, and tail subdivisions.

II. **Head** region composition

A. **Efferent ducts**

1. Connect rete testis with duct of epididymis

2. Are about 12 in number, each of which is coiled into a cone shape. Each coiled efferent duct, with its surrounding connective tissue and abundant blood vessels, forms a **conus vasculosus (plural coni vasculosi)**.

3. Each duct connects with the rete testis at the apex of the cone adjacent to the testis. All ducts anastomose to form the single duct of the epididymis at the bases of the cones.

4. Are lined with a simple epithelium composed of alternating taller, ciliated cells and shorter cuboidal cells with lysosomes. Therefore, efferent ducts present a characteristic, scalloped border adjacent to the lumen. A thin muscularis layer surrounds the epithelium.

5. Function. Ciliated cells propel spermatozoa toward duct of epididymis while cuboidal cells absorb testicular fluid.

B. **Duct of epididymis**. A single duct formed by fusion of efferent ducts

III. **Body and tail regions**

A. Contains the remainder of the duct of the epididymis

1. Highly coiled, single tube (6 m long) formed by union of efferent ducts in the head region

2. Lined by tall **pseudostratified columnar epithelium with stereocilia**, which decreases in height from head to tail regions; creates a smooth lumen when compared with efferent ducts

3. Smooth muscle layer surrounds epithelium and increases in thickness and number of layers from head to tail

B. Function

1. Storage and maturation site for sperm

2. Absorption of excess testicular fluid

3. Movement of sperm toward ductus deferens

DUCTUS (VAS) DEFERENS *(images)*

I. The **ductus deferens** is a direct continuation of the duct of the epididymis carrying sperm to the ejaculatory duct.

II. Structure

A. Mucosa

1. Pseudostratified columnar epithelium with stereocilia surrounds a narrow

lumen.

2. Thin lamina propria

3. Longitudinal folds produce an irregular lumen.

B. Thick muscularis. Inner and outer longitudinal, middle circular layers of smooth muscle

III. Course

A. Located in **spermatic cord** in the inguinal canal along with:

1. **Spermatic artery**. Carries oxygenated and nutrient-rich blood to the tests.

2. **Pampiniform plexus**. Plexus of veins returning blood from the testis. Surrounds the spermatic artery forming a counter-current cooling mechanism to reduce the temperature of the blood entering the testis. Spermatogenesis requires temperatures less than normal body temperature.

3. **Cremaster muscle**. Skeletal muscle that elevates and lowers the testis relative to the body surface, aiding in maintaining lower intra-testicular temperature.

4. Nerve plexus.

B. Enters abdominal cavity, crosses above entrance of ureter into bladder, and enlarges to form the **ampulla**, which lies posterior to urinary bladder

C. Is joined by duct of the seminal vesicle just before it enters the prostate

IV. Function. Transports and propels sperm from the epididymis to the ejaculatory duct which travels through the prostate gland.

EJACULATORY DUCT

I. Each ejaculatory duct is formed by the union of a ductus deferens with the **duct of a seminal vesicle**.

II. No muscle layer is retained from the ductus deferens.

III. Each ejaculatory duct traverses the prostate gland to join the prostatic urethra.

URETHRA

I. **Prostatic urethra**. Within prostate; lined with transitional epithelium

II. **Membranous urethra**. Pierces skeletal muscle of the urogenital diaphragm; lined with stratified or pseudostratified columnar epithelium

II. **Penile urethra** (discussed with penis)

GENITAL GLANDS

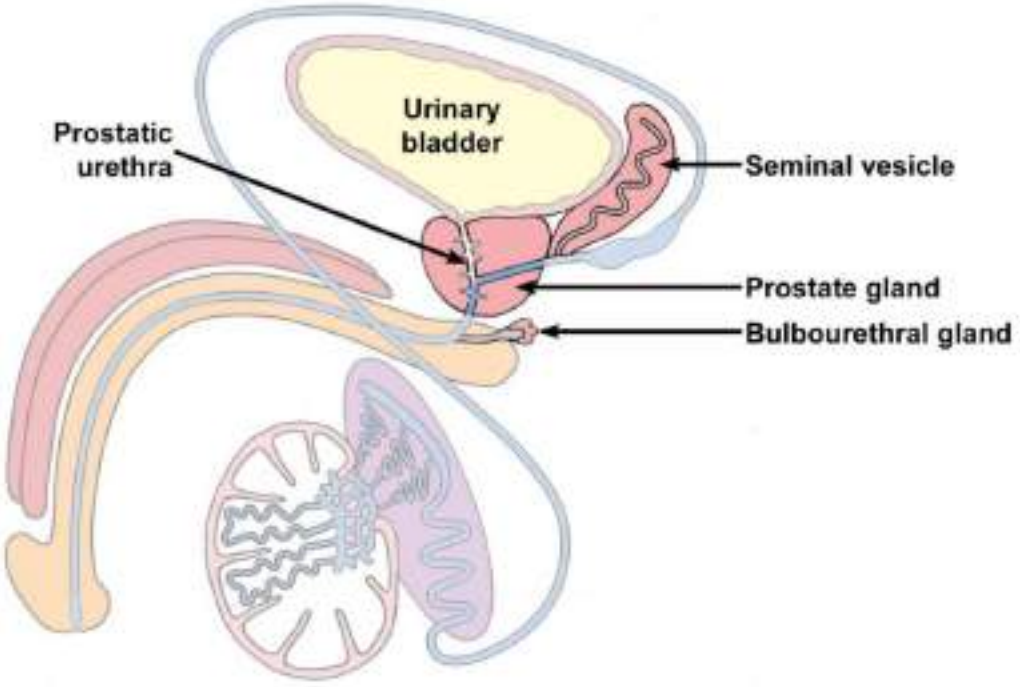

FIGURE 17.6. Major glands and their associated passageways.

SEMINAL VESICLE *(images)*

I. **Seminal vesicles** are paired glands lying posterior to the urinary bladder.

II. Each is composed of a single, highly tortuous tube.

III. Secretions.

1. Produces viscous, alkaline yellowish secretion that forms 70% of the total ejaculate.

2. Components of the secretion.

a. Fructose. Major energy source for sperm.

b. Prostaglandins, ascorbic acid and other simple sugars.

c. Seminogelin. Semen coagulation factor.

IV. Structure

A. Pseudostratified columnar epithelium with many secretory granules overlies a thin layer of connective tissue. These tissues are thrown into an intricate system of primary, secondary, and tertiary folds that produce a pattern of arcades, dividing the central lumen into fragments.

B. A thin layer of smooth muscle surrounds the tube.

PROSTATE GLAND *(images)*

I. The **prostate**, a single, midline gland, is the largest of the genital glands and surrounds the prostatic urethra.

II. 30-50 tubuloalveolar glands, opening onto the prostatic urethra, can be divided into groups depending on their location.

A. **Periurethral glands**. Immediately surround the prostatic urethra (5%). Excessive growth causes benign prostatic hyperplasia (BPH)

B. **Submucosal glands**. 25%

C. **Main glands**. Located toward the periphery of the gland (70%). Source of prostate cancers.

III. Capsule. Dense connective tissue with abundant smooth muscle; septa from the capsule also possesses smooth muscle fibers and partition the gland into indistinct lobes.

IV. Usually lined by a pseudostratified columnar epithelium whose height will vary with its activity

V. **Prostatic concretions**. Lamellated, spherical bodies that are the condensation of secretory products. The number of concretions increases with age.

VI. Secretions.

A. Contributes a thin, clear, slightly alkaline secretion.

B. Components of the secretion.

1. Citric acid, acid phosphatase and zinc.

2. Prostate specific antigen (PSA)

3. Fibrinolysin. Proteases that liquefies the congealed semen resulting from the coagulation produced by semenogelin in seminal vesicle secretion. This liquefaction of the seminal coagulum liberates the sperm, thus allowing them to enter the endocervical canal of the uterus.

BULBOURETHRAL GLAND (COWPER'S GLAND)

I. Paired, pea-sized glands.

II. Duct enters the initial portion of the penile urethra.

III. Mucous secretion (pre-seminal fluid)

PENIS *(images)*

COMPOSITION

I. Three cylindrical masses of erectile tissue

   A. **Corpora cavernosa**. Paired dorsal cylinders

   B. **Corpus spongiosum** (corpus cavernosum urethrae)

      1. Single, ventral cylinder that houses the penile urethra

      2. Expands to terminate in glans penis that caps the two corpora cavernosa

II. Structure

   A. Outer covering of skin (epidermis and dermis)

   B. **Tunica albuginea**

      1. Capsule of dense, nonelastic connective tissue surrounding the three cylinders

      2. Thicker around corpora cavernosa than around corpus spongiosum

      3. Forms an incomplete septum between the corpora cavernosa

   C. Structure of erectile tissue

1. Sponge-like **cavernous spaces** (venous spaces) separated by connective tissue trabecula with smooth muscle fibers

2. Deep artery in each corpus cavernosum supplies blood to:

    a. Nutritive arteries that supply trabecula

    b. **Helicine arteries** that supply cavernous spaces

PROCESS OF ERECTION

I. Flaccid state is effected by a minimal blood flow to the penis. This blood flow is regulated by the continuous input of the sympathetic division of the autonomic nervous system on the tone of the smooth muscle in the penile vasculature.

II. Erection

    A. Parasympathetic division of autonomic nervous system effects relaxation of smooth muscle (vasodilation) of the deep and helicine arteries.

    B. The subsequent filling of the cavernous spaces expands these vessels against the tunica albuginea, causing the penis to become erect and turgid.

    C. Corpus spongiosum does not become as erect as the other cavernous bodies because its tunica albuginea is thinner. Therefore, sperm can be transported during ejaculation.

III. Return to flaccid state occurs with decline of parasympathetic activity and increased sympathetic activity to constrict the helicine arteries.

PENILE URETHRA

I. The **penile urethra** is located within corpus spongiosum (corpus cavernosum urethrae).

II. Microscopic anatomy

    A. Lined by pseudostratified columnar epithelium that becomes stratified squamous moist in fossa navicularis, the terminal enlargement in the glans penis

    B. **Glands of Littre**

        1. Mucus-secreting glands

        2. Originate in mucus-secreting recesses of the urethra and extend obliquely

toward the base of the penis

3. Secrete a mucous fluid that is the initial ejaculate; provides lubrication

CHAPTER 8

NERVOUS TISSUE

GENERAL CONCEPTS

I. Nervous tissue is highly specialized to employ modifications in membrane electrical potentials to relay signals throughout the body. Neurons form intricate circuits that:

   A. Relay sensory information from the internal and external environments.

   B. Integrate information among millions of neurons

   C. Transmit effector signals to muscles and glands.

II. Anatomical subdivisions of nervous tissue

   A. **Central nervous system (CNS)**

      1. **Brain**

      2. **Spinal cord**

   B. **Peripheral nervous system (PNS)**

      1. **Nerves**

      2. **Ganglia (singular, ganglion)**

CELLS OF NERVOUS TISSUE

I. **Neurons**

   A. Functional units of the nervous system; receive, process, store, and transmit information to and from other neurons, muscle cells, or glands

   B. Composed of a cell body, dendrites, axon and synapses

   C. Form complex and highly integrated circuits

II. **Supportive cells**

   A. Provide metabolic and structural support for neurons, insulate neurons via a

myelin sheath, maintain homeostasis, and perform phagocytic functions

B. Comprised of astrocytes, oligodendrocytes, microglia, and ependymal cells in the CNS; comprised of Schwann cells in the PNS

STRUCTURE OF A "TYPICAL" NEURON

I. **Cell body (soma, perikaryon)**

A. **Nucleus**

1. Large, spherical, usually centrally located in the soma

2. Highly euchromatic with a large, prominent nucleolus

B. **Cytoplasm**

1. Well-developed cytoskeleton

a. Intermediate filaments *(neurofilaments)*

b. Microtubules

2. Abundant rough endoplasmic reticulum and polysomes *(***Nissl substance***)*

3. Well-developed Golgi apparatus

4. Numerous mitochondria

II. **Dendrite(s)**

A. Usually multiple and highly branched at acute angles

B. May possess **spines** small membranous elevations which form excitatory synapses

C. Collectively, form the majority of the receptive field of a neuron; conduct impulses toward the cell body

D. Cytoplasmic components

1. Microtubules and neurofilaments

2. Rough endoplasmic reticulum and polysomes

3. Smooth endoplasmic reticulum

4. Mitochondria

III. **Axon**

A. Usually only one per neuron

B. Generally of smaller caliber and longer than dendrites

C. Branches at right angles, fewer branches than dendrites

D. Cytoplasmic components

1. Microtubules and neurofilaments

2. Lacks rough endoplasmic reticulum and polysomes

3. Smooth endoplasmic reticulum

4. Mitochondria

E. **Axon hillock**. Region of the cell body where axon originates

1. Devoid of rough endoplasmic reticulum and so stains pale

2. Continuous with **initial segment** of the axon that is a highly electrically excitable zone for initiation of nervous impulse

F. Usually ensheathed by supporting cells

G. Transmits impulses away from the cell body to

1. Neurons

2. Effector structures such as muscle and glands

H. Branches extensively near its target, each branch ends in a swelling, the terminal bouton, which is the presynaptic element of a synapse

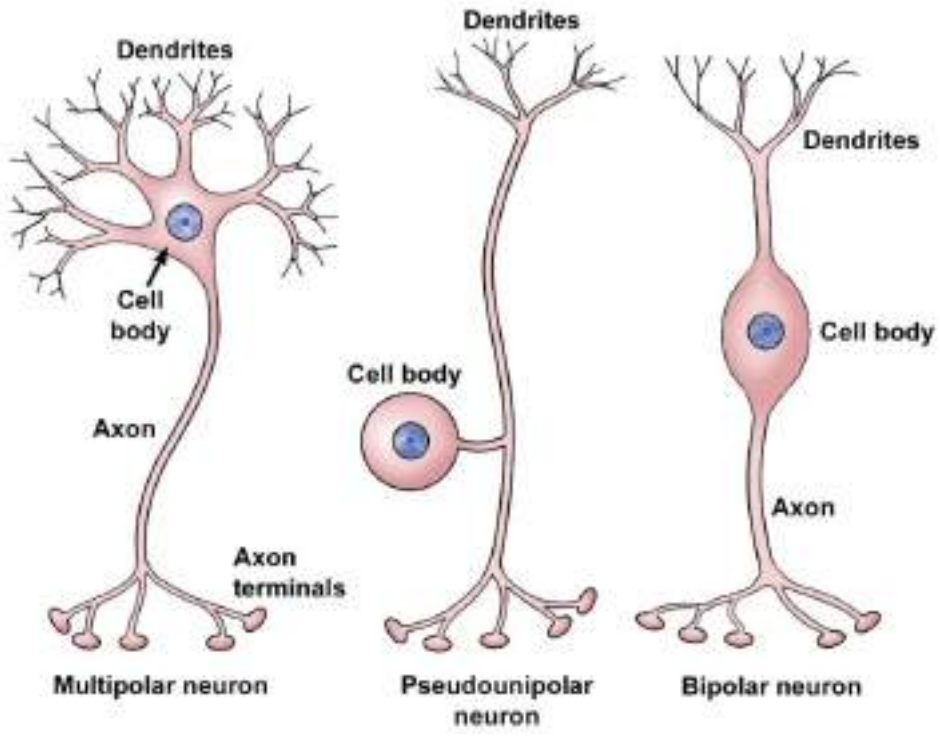

FIGURE 8.1. Types of neurons based on shape.

TYPES OF NEURONS BY SHAPE AND FUNCTION *(images)*

I. **Multipolar neuron**. Most numerous and structurally diverse type

   A. Efferent. Motor, carrying impulses out of the CNS or innervating smooth muscle from autonomic ganglia

   B. Integrative function, axons remain in the CNS

   C. Found throughout the CNS and in autonomic ganglia in the PNS

II. **Pseudounipolar neuron**

   A. Afferent. Sensory function, carrying impulses from peripheral receptors into the CNS

   B. Found in selected areas of the CNS and in sensory ganglia of cranial nerves and spinal nerves (dorsal root ganglia)

III. **Bipolar neuron**

   A. Afferent. Sensory function

B. Found associated with organs of special sense (retina of the eye, olfactory epithelium, vestibular and cochlear ganglia of the inner ear)

C. Developmental stage for all neurons

ARRANGEMENT OF NEURONAL CELL BODIES AND THEIR PROCESSES

I. In both CNS and PNS, cell bodies are found in clusters or layers and axons travel in bundles. These groupings are based on common functions and/or common connections.

	Group of cell bodies	**Bundle of processes**
Central nervous system	Nucleus or cortex (gray matter)	Tract (white matter)
Peripheral nervous system	Ganglion	Nerve

SYNAPSE

I. The function of the synapse is to alter the membrane potential of the postsynaptic target cell to either facilitate or inhibit the likelihood of the stimulus to be propagated by the postsynaptic cell. Most neurons receive thousands of synaptic contacts, both stimulatory and inhibitory, and the algebraic sum of these inputs determines whether the postsynaptic cell will depolarize.

II. Classified according to postsynaptic target

A. **Axodendritic**. Most common

B. **Axosomatic**

C. **Axoaxonic**. Occur mostly at presynaptic terminals

D. **Neuromuscular junction**

III. Structure of the synapse ***(images)***

A. **Presynaptic component**

1. Distal end of the axon branches, each branch terminating in a swelling or button called the **terminal bouton.**

2. Boutons with neurotransmitter-containing *synaptic vesicles* and numerous mitochondria.

B. **Synaptic gap/cleft**. Separation (20-30 nm) between pre- and postsynaptic cells.

C. **Postsynaptic component**

1. Formed by the membrane of the postsynaptic neuron or muscle cell and contains receptors for neurotransmitters

2. Membrane shows a **postsynaptic density** or thickening on its cytoplasmic side.

D. **Bouton en passant**. "Bouton-like" swellings along the length of an axon, allow a single axon to contact many distant cells. Common in smooth muscle innervation.

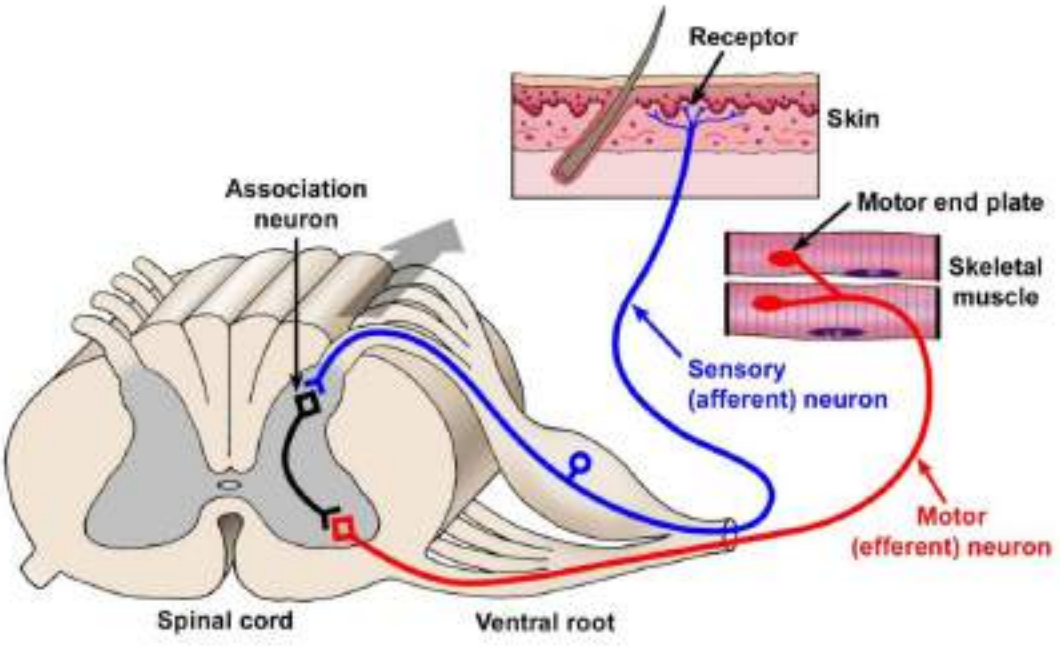

FIGURE 8.2. The reflex arc.

THE REFLEX ARC

I. The reflex arc is the simplest neuronal circuit and includes each of the elements discussed above. These circuits provide rapid, stereotyped reactions to help maintain homeostasis. To begin the reflex, a pseudounipolar, sensory neuron is activated by a receptor. The axon carries an afferent signal from the skin into the spinal cord where it synapses on a multipolar association neuron or interneuron. The interneuron signals a multipolar, motor neuron whose axon then carries an efferent signal to skeletal muscle to initiate contraction.

SUPPORTIVE CELLS

I. Supporting cells of the CNS (neuroglial cells) ***(images)***

A. **Astrocytes**

1. Stellate morphology
2. Types
    a. **Fibrous astrocytes** in white matter
    b. **Protoplasmic astrocytes** in gray matter
3. Functions
    a. Physical support
    b. Transport nutrients
    c. Maintain ionic homeostasis
    d. Take up neurotransmitters
    e. Form glial scars (gliosis)

B. **Oligodendrocytes**

1. Present in white and gray matter
2. **Interfascicular oligodendrocytes** are located in the white matter of the CNS, where they produce the myelin sheath.
3. **Perineuronal (satellite) oligodendrocytes** are located in regions of grey matter near neuronal cell bodies

C. **Ependymal cells**. Line ventricles, ciliated.

D. **Microglia**

1. Not a true neuroglial cell; derived from the yolk sac, whereas neuroglial cells, as well as neurons, are derived from ectoderm
2. Highly phagocytic cells
3. Provide immune surveillance and produce immunomodulatory compounds

II. Supporting cells of the PNS. **Schwann cells *(images)***

A. **Satellite Schwann cells** surround cell bodies in ganglia

B. **Ensheathing Schwann cells**

1. Surround unmyelinated axons. Numerous axons indent the Schwann cell cytoplasm and, therefore, are surrounded by a single plasma membrane.

2. Produce the myelin sheath around axons

MYELIN SHEATH *(images)*

I. The **myelin sheath** is formed by the plasma membrane of supporting cells wrapping around the axon. The sheath consists of multilamellar, lipid-rich segments produced by Schwann cells in the PNS and oligodendrocytes in the CNS.

II. Functions

A. Increases speed of conduction *(***saltatory conduction***)*

B. Insulates the axon

III. Similar structure in CNS and PNS with some differences in protein composition

IV. Organization

A. **Internode***.* Single myelin segment

B. **Paranode***.* Ends of each internode where they attach to the axon

C. **Node of Ranvier***.* Specialized region of the axon between myelin internodes where depolarization occurs

V. In the PNS, each Schwann cell associates with only one axon and forms a single internode of myelin.

VI. In the CNS, each oligodendrocyte associates with many axons (i.e. each oligodendrocyte forms multiple internodes on different axons).

CONNECTIVE TISSUE INVESTMENTS OF NERVOUS TISSUE

I. Peripheral nervous system ***(images)***

A. **Endoneurium***.* Delicate connective tissue surrounding Schwann cells;

includes the basal lamina secreted by Schwann cells as well as reticular fibers

B. **Perineurium**. Dense tissue surrounding groups of axons and their surrounding Schwann cells, forming fascicles; forms the blood-nerve barrier

C. **Epineurium**. Dense connective tissue surrounding fascicles and the entire nerve

II. Central nervous system (**meninges**)

A. **Pia mater**

1. Thin membrane lying directly on the surface of the brain and spinal cord

2. Accompanies larger blood vessels into the brain and spinal cord

B. **Arachnoid membrane**

1. Separated from pia mater by connective tissue trabeculae

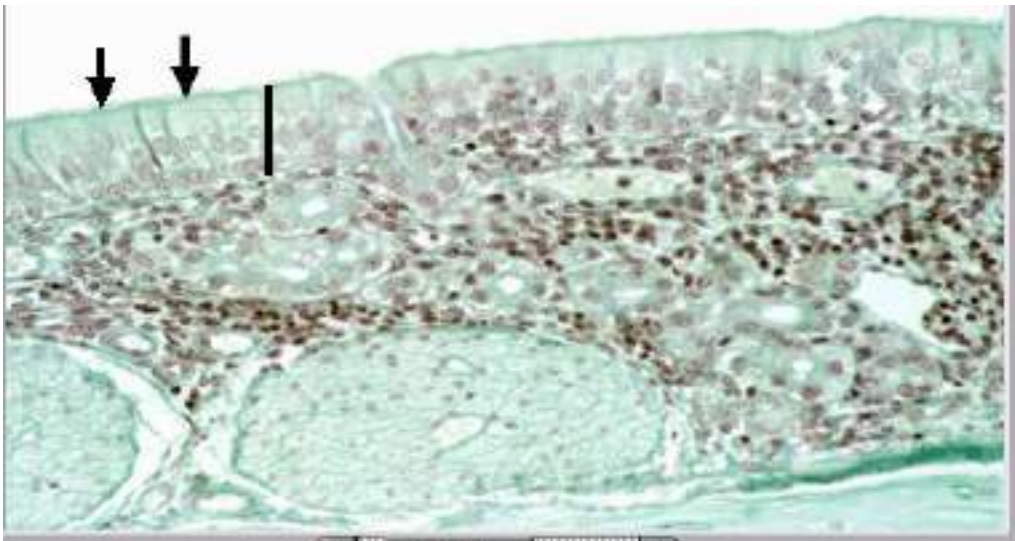
2. Encloses the **subarachnoid space**, which contains blood vessels and the **cerebrospinal fluid (CSF)** produced by the cells of the choroid plexus

3. Together with pia mater, constitute the **leptomeninges**; inflammation of these membranes produces meningitis

C. **Dura mater**

1. Outermost of the meninges

2. Dense connective tissue that includes the periosteum of the skull

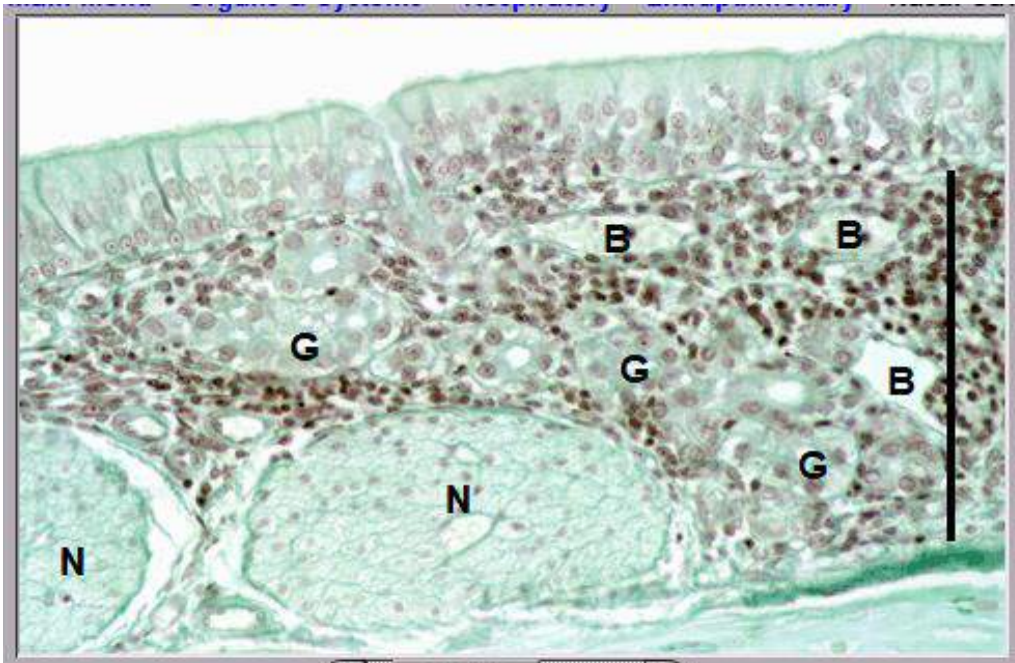


click to identify:

> Pseudostratified > columnar epithelium
CT >
Bone >

2 of 6

The epithelium lining most of the nasal cavities is a thin, respiratory epithelium: pseudostratified columnar epithelium (bar) with cilia (arrows) and goblet cells (which are not readily visible here, probably because this is fetal tissue and these cells are not functional yet).



click to identify:

Pseudostratified > columnar epithelium
> CT >
Bone >

2 of 6

Because the nasal cavity lacks a muscularis mucosae, the connective tissue (bar) beneath the epithelium is a combination of lamina propria in continuity with submucosa. Numerous glands (G) (mixed glands, when functional after birth) are seen, as are numerous blood vessels (B) to moderate air temperature. Sensory, peripheral nerves (N) also traverse this layer.

2 of 6

All the extra-pulmonary structures of the respiratory system are supported by either bone or cartilage to maintain patency. In the nasal cavity both cartilage and bone are present in different locations to keep this passageway open.

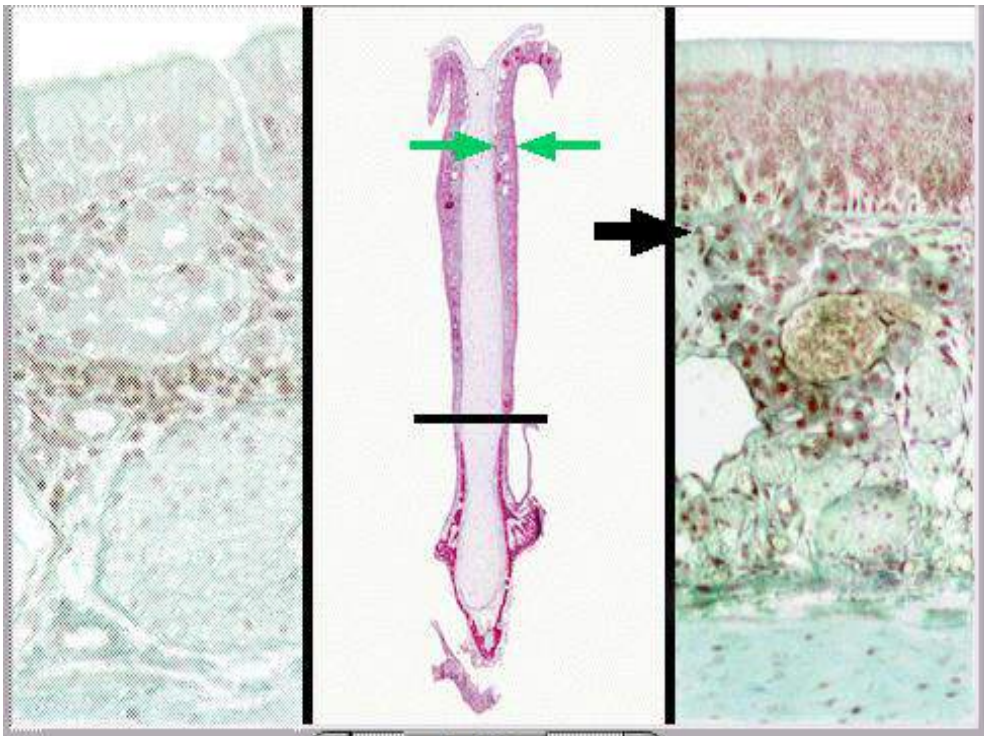
3 of 6

The nasal septum separates the two nasal cavities (nasal fossae, NC). Cartilage forms the central frame of this fetal septum. Note that the olfactory mucosa (green arrows) above the horizontal bar is much thicker than the respiratory mucosa (blue arrows) below the bar.



click to identify:

Nasal septum >
Respiratory > mucosa
› Olfactory > mucosa
Cartilage / bone >

3 of 6

The thicker olfactory mucosa, above the bar, lines the superior portion of the septum and is seen at higher magnification on the right and in the next image.

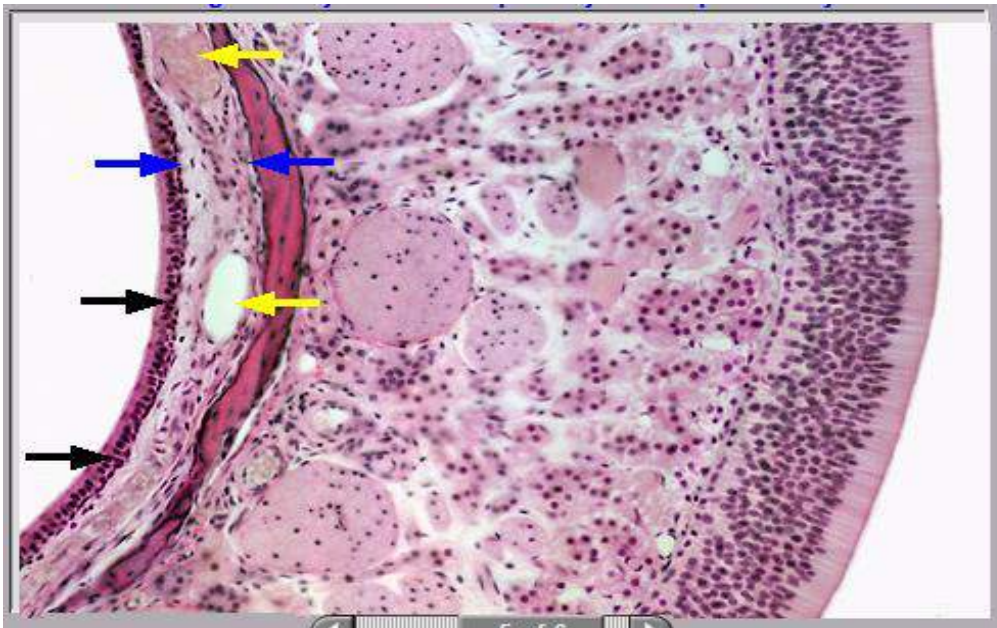
5 of 6

The outline in the inset shows the location from which this section was taken, including the superior concha (arrow) extending into the superior region of the nasal cavity. The location of the olfactory epithelium covering the medial surface of this concha is colored purple; non-olfactory epithelium lines the lateral surface of the concha.



5 of 6

Respiratory mucosa lines the non-olfactory region of the nasal fossae, represented here by the lateral surface of a superior concha. This mucosa possesses a pseudostratified columnar epithelium (black arrows) with cilia and goblet cells. The underlying connective tissue (between blue arrows) is rich in blood vessels (yellow arrows) to moderate air temperature.

click to identify:

- Orientation >

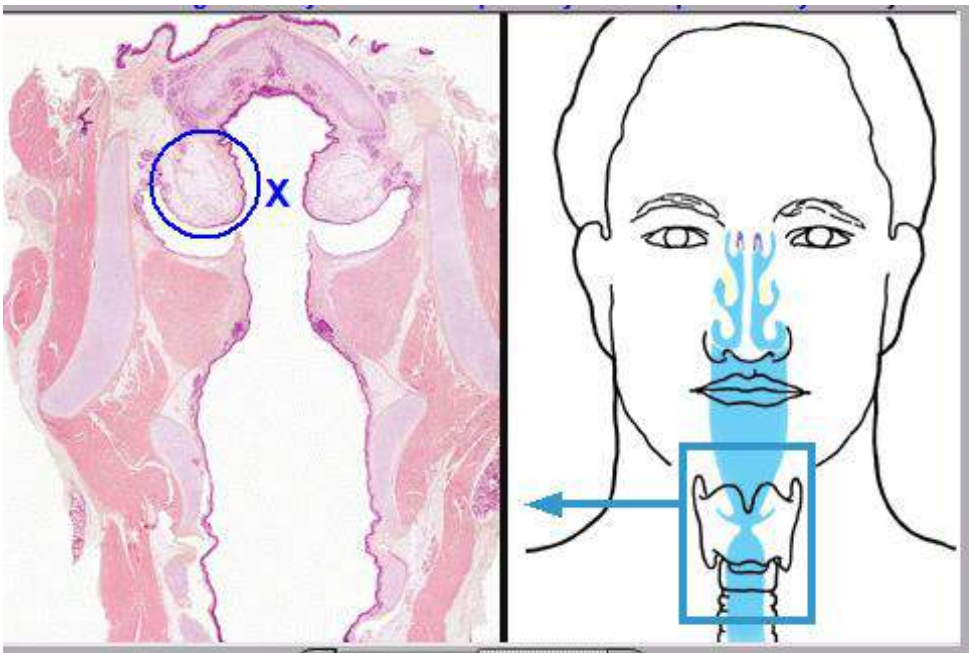
Cartilagenous support for the larynx is provided by three large cartilages and multiple smaller ones (not seen here). The epiglottis (A, elastic cartilage) guards the entrance to the larynx. The large thyroid cartilage (B, hyaline) protects the anterior and lateral sides, and the cricoid (C) cartilage (hyaline) encircles the larynx, providing the major posterior support.



1 of 2

The paired false vocal folds lie superior to the true vocal folds. The false folds are covered by pseudostratified columnar epithelium overlying a connective tissue containing adipose tissue and mixed, mucoserous glands. The vestibule (X) separates the two false vocal folds.

1 of 2

Each true vocal fold houses a vocalis muscle (A, skeletal) that alters the length of the fold. The vocal ligament (dense regular elastic connective tissue) maintains tautness in the edge of the fold but cannot be differentiated from collagen with this H and E stain. Stratified squamous moist epithelium (arrow) covers the fold. The ventricle (X) lies between the two folds.

1 of 2

Laryngeal epithelium varies depending on the stress it undergoes. Stratified squamous moist epithelium (A) normally lines the epiglottis and the true vocal folds, areas that undergo continual stress. Respiratory epithelium (B), lining the remainder of the larynx, may be converted to stratified squamous moist in cases of irritation, such as in the larynx of a smoker.

The deepest layer of the mucosa is a band of elastic fibers, the elastic lamina. Elastic fibers run longitudinally throughout the respiratory passageways, but are only organized into a definitive layer, the elastic lamina, in the trachea and primary bronchi. Elastic fibers aid in passive expiration of air from the lungs and respiratory passageways.

A secondary bronchus is identified by a mucosa of pseudostratified columnar epithelium with cilia and goblet cells (E), lamina propria (L), and a muscularis mucosae (M). Beaneath the mucosa are two layers: a submucosa (S) with mixed glands (G) and cartilagenous plates (C). (Some of the glands are atypical in that they are located beneath the cartilage rather than in the submucosa.)

Alveoli are visible in this field and, therefore, these larger passageways are intrapulmonary. The lumens of the alveoli, however, are not continuous with those of the secondary bronchi and bronchioles and, therefore, these larger passageways are not capable of gas exchange.

Bronchiole -- At higher magnification the components of the wall of a bronchiole are apparent. This is a larger bronchiole because it is lined by pseudostratified columnar epithelium with cilia and goblet cells. Abundant, longitudinally arranged elastic fibers are located in lamina propria. Muscularis mucosae is composed of spiraling bands of smooth muscle. 200x

CHAPTER 13

RESPIRATORY SYSTEM

OVERVIEW

COMPONENTS OF THE RESPIRATORY SYSTEM

I. In relationship to lungs (listed in order from exterior to interior, i.e., the path of inspired air)

   A. Extrapulmonary

      1. Nasal cavity

      2. Pharynx

      3. Larynx

      4. Trachea

      5. Primary bronchi

   B. Intrapulmonary

      1. Secondary bronchi

      2. Bronchioles

      3. Terminal bronchioles

      4. Respiratory bronchioles

      5. Alveolar ducts

      6. Alveoli

II. According to function (listed in order from exterior to interior

   A. Conducting Portion (Transports air from exterior)

      1. Nasal cavity

      2. Pharynx

3. Larynx
4. Trachea
5. Primary bronchi
6. Secondary bronchi
7. Bronchioles
8. Terminal bronchioles

B. Respiratory Portion (Involved with gas exchange)

1. Respiratory bronchioles
2. Alveolar ducts
3. Alveoli

STRUCTURAL ORGANIZATION OF RESPIRATORY PASSAGEWAYS

I. Conducting portion (nasal cavities through secondary bronchi)

A. Mucosa (mucous membrane). Faces the lumen

1. **Respiratory epithelium. Pseudostratified with cilia and goblet cells***.*

2. Lamina propria of loose connective tissue with blood vessels and nerves

3. Deepest layer of mucosa may consist of:

a. An **elastic lamina** or

b. A **muscularis mucosae** or

c. This layer may be absent.

B. **Submucosa***.* Dense irregular connective tissue with mucous and serous (mixed) glands

C. **Cartilage** or **bone**

D. **Adventitia***.* Loose connective tissue forming the outer layer of the passageway

II. Structural transitions in walls and layers of the passageways from extrapulmonary passageways to alveoli

A. Transitions

1. Layers become thinner as passageways decrease in diameter.

2. Epithelium decreases in height from pseudostratified to simple columnar to simple cuboidal to simple squamous.

3. Goblet cells and mixed glands stop relatively abruptly at the junction of a secondary bronchus with a bronchiole.

4. Cartilage decreases in size, breaks up into plates, and stops relatively abruptly at the junction of a secondary bronchus with a bronchiole.

5. Cilia are gradually eliminated.

B. Results in the formation of the wall of an **alveolus**, where gas exchange occurs

1. Epithelium is simple squamous

2. Connective tissue core with numerous capillaries

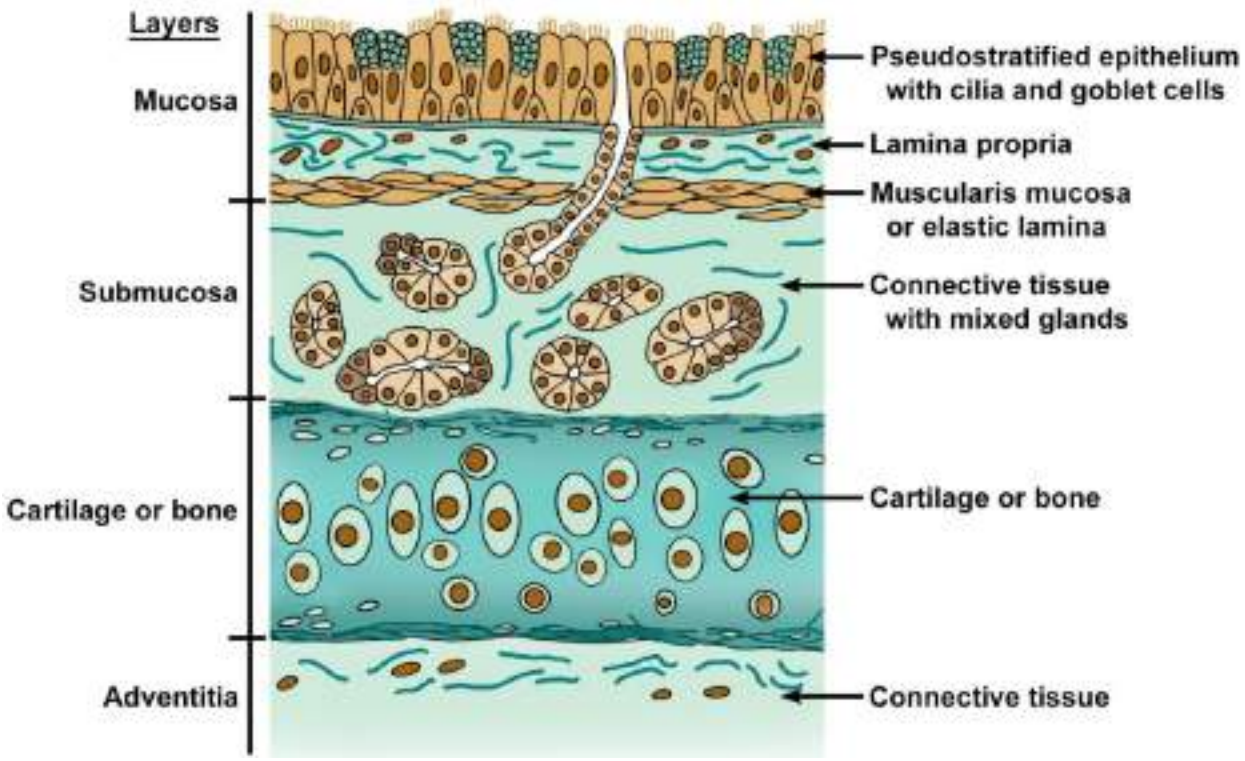

FIGURE 13.1. Layers and components of respiratory passageways.

CONDUCTING PORTION

NASAL CAVITIES (EXTRAPULMONARY) *(images)*

I. The nasal cavities can be subdivided into two regions, the olfactory and the non-olfactory regions.

II. **Non-olfactory region**

A. **Vestibules**. The epithelium undergoes a transition from epidermis of skin with hairs to pseudostratified, respiratory epithelium, with cilia.

B. **Nasal fosse**

1. Typical mucosa but deepest layer is lacking (i.e., neither a muscularis mucosae nor an elastic lamina is present)

2. Patency maintained by bones or cartilage.

C. **Olfactory region**

1. Upside-down, U-shaped area in posterior, superior region of each nasal fossa, extending over a superior concha and about 1 cm down nasal septum

2. Composition of wall

a. Mucosa

i. Epithelium is tall, thick, **pseudostratified columnar** with nonmotile cilia. The epithelium is composed of:

(a). **Olfactory cells** (neurons). Bipolar neurons that respond to odors. A single dendrite extends to the surface to form a swelling, the **olfactory vesicle**, from which nonmotile cilia extend over the surface. These cilia increase surface area and respond to odors.

(b). **Support cells** span the epithelium and support the olfactory cells.

(c). **Basal cells** are located on the basal lamina and serve as reserve cells for the epithelium.

ii. Deepest layer of mucosa is not present, so the lamina propria blends with the submucosa. This connective tissue layer contains

Bowman's glands, serous glands whose watery secretions flush odorants from the epithelial surface.

b. Patency maintained by bone.

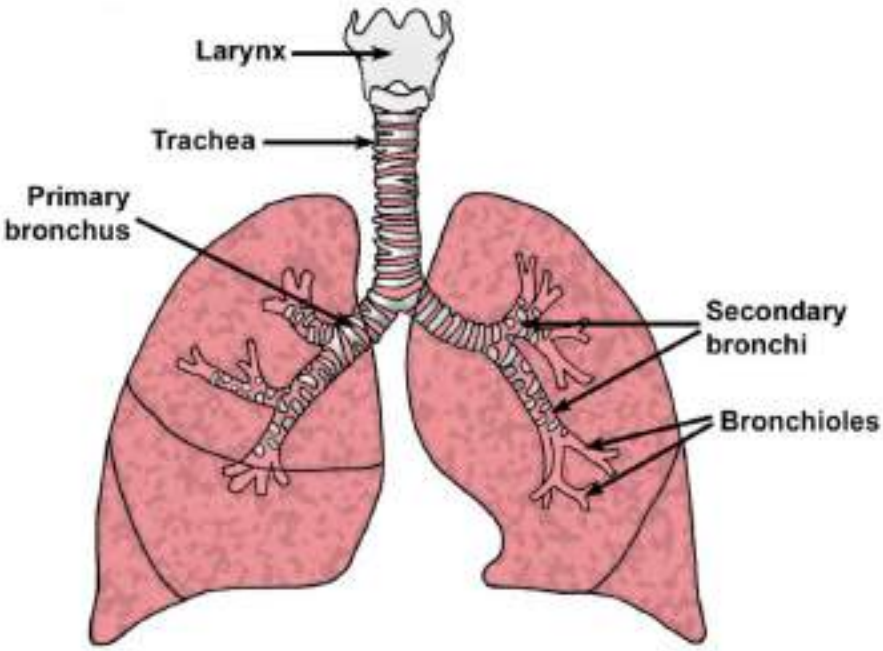

FIGURE 13.2. Conducting portion of the respiratory system.

LARYNX (EXTRAPULMONARY) *(images)*

I. Composition of the wall of the **larynx**

A. Mucosa

1. Epithelium

a. Pseudostratified with cilia and goblet cells in most areas

b. Stratified squamous moist over true vocal folds and much of epiglottis because of friction incurred in these areas

2. No muscularis mucosae or elastic lamina, so lamina propria is continuous with submucosa.

B. Submucosa with mixed glands (except in true vocal fold)

C. Cartilages maintaining patency are numerous, uniquely shaped and are either hyaline or elastic. The larger cartilages are the **epiglottis**, **thyroid**,

and **cricoid**.

D. An adventitia is present.

II. Vocal apparatus. Modification in the larynx composed of two pairs of horizontally positioned mucosal folds located on the lateral walls of the larynx.

A. **False vocal folds**. More superior in location. Resemble the wall of a typical respiratory passageway except the deepest layer of the mucosa is absent (no muscularis mucosae nor elastic lamina).

B. The **ventricle**, a space, separates the false from the true vocal folds.

C. **True vocal folds**

1. Are lined by a stratified squamous moist epithelium and its lamina propria

2. A **vocal ligament** of dense regular elastic connective tissue is located at the edge of the fold, keeping the rim of the fold taut.

3. **Vocalis muscle**, skeletal muscle, lies within each true vocal fold. This muscle alters the shape of the vocal fold and aids in phonation.

TRACHEA AND PRIMARY BRONCHI (EXTRAPULMONARY) ***(images)***

I. The **trachea** and **primary bronchi** are identical in structure and will be considered together.

II. Mucosa

A. Epithelium is pseudostratified with cilia and goblet cells with a very prominent basement membrane

B. Lamina propria of loose connective tissue

C. Elastic lamina of longitudinally arranged elastic fibers

III. Submucosa with mixed glands

IV. **C-shaped cartilage** rings maintain patency; **trachealis muscle** (smooth) interconnects the open ends of the tracheal rings.

V. Adventitia is present.

SECONDARY BRONCHI (INTRAPULMONARY) ***(images)***

I. **Secondary bronchi**

A. The first intrapulmonary structures; a secondary bronchus supplies each of the three lobes of the right lung and the two lobes of the left lung.

B. Similar to, but diminished in size from, the primary bronchi

II. Mucosa

A. Epithelium, pseudostratified with cilia and goblet cells

B. Lamina propria contains numerous, longitudinally arranged elastic fibers.

C. Muscularis mucosae of smooth muscle fibers arranged in crisscrossing bands

III. Submucosa with mixed glands

IV. Patency maintained by **plates of hyaline cartilage***.*

V. Adventitia is present.

BRONCHIOLES (INTRAPULMONARY) ***(images)***

I. Walls of **bronchioles** continue to decrease in size. The greatest changes in histology occur in the walls of the bronchioles as glands and cartilage are eliminated.

II. Mucosa

A. Epithelium

1. Pseudostratified with cilia and goblet cells in largest bronchioles that decreases to:

2. Simple columnar with cilia in smallest bronchioles **(terminal bronchioles)**, but no goblet cells persist.

3. **Clara cells** are present in terminal bronchioles.

a. Tall, dome-shaped, nonciliated cells

b. Possess numerous secretory granules whose contents aid in lowering surface tension of the terminal bronchioles, thus aiding in inspiration

B. Lamina propria contains numerous, longitudinally arranged elastic fibers.

C. Muscularis mucosae. Greatest development of smooth muscle (crisscrossing

bands) in relationship to thickness of wall of all respiratory passageways

III. Submucosa contains no glands.

IV. No cartilages or bones support bronchioles; therefore, submucosa and adventitia form a single connective issue layer.

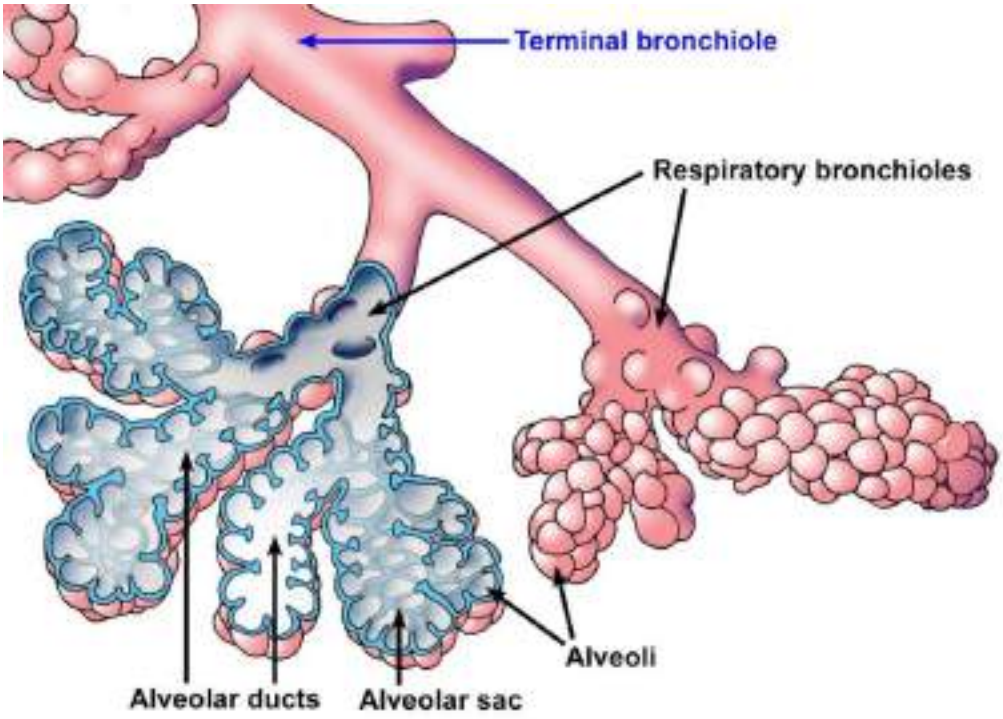

FIGURE 13.3. Components of the respiratory portion of the respiratory system.

RESPIRATORY PORTION

PRIMARY FUNCTION

I. Gas exchange occurs in the alveolus. Therefore, an alveolus must be an integral part of all the passageways of the respiratory part of the respiratory system.

RESPIRATORY BRONCHIOLES *(images)*

I. **Respiratory bronchioles** continue to decrease in diameter and in thickness of their walls.

II. Mucosa.

A. Simple cuboidal epithelium with Clara cells and a few sparsely scattered cilia

B. Longitudinal arranged elastic fibers in lamina propria

C. Muscularis mucosae of smooth muscle

III. Alveoli bulge from wall (i.e., lumen of alveolus is continuous with lumen of respiratory bronchiole).

ALVEOLAR DUCTS *(images)*

I. An **alveolar duct** is formed as the alveoli in a respiratory bronchiole increase in number, thereby decreasing the amount of wall that is present.

A. At the level of the alveolar duct, the "wall" is reduced to a series of rings framing the entrance to an alveolus or a group of alveoli (alveolar sac).

B. When sectioned, these rings resemble knobs to which the alveoli are attached.

II. Wall

A. Simple cuboidal epithelium

B. Elastic fibers and smooth muscle in "knobs"

C. Alveoli bulge from the framework formed by the knobs.

ALVEOLAR SACS

I. **Alveolar sacs** are two or more alveoli arising from a single ring of knobs.

ALVEOLI *(images)*

I. **Alveoli** are thin-walled, hollow polyhedrons forming the bulk of the lungs; where gas exchange occurs.

II. Individual alveoli are components of respiratory bronchioles and alveolar ducts, or multiple alveoli may be grouped together to form alveolar sacs.

III. **Interalveolar septum**. Structure between two adjacent alveoli is composed of:

A. The epithelium lining each alveolus.

1. **Squamous alveolar or type I cells** form a simple squamous epithelium lining 95% of the alveolar surface area and forming a portion of the blood-air barrier.

2. **Septal or type II cells**

    a. Spherical cells with microvilli and abundant, vacuolated cytoplasm; bulge into alveolar space

    b. **Lamellar bodies** in the cytoplasm of septal cells are responsible for the vacuolated appearance of these cells. Lamellar bodies give rise to surfactant, a secretory product consisting of phospholipids, glycosaminoglycans, and proteins.

    c. Serve as progenitors for both type I and type II cells

B. Connective tissue core contains a vast capillary bed that bulges into the alveolar space, elastic fibers, alveolar macrophages, and other connective tissue components.

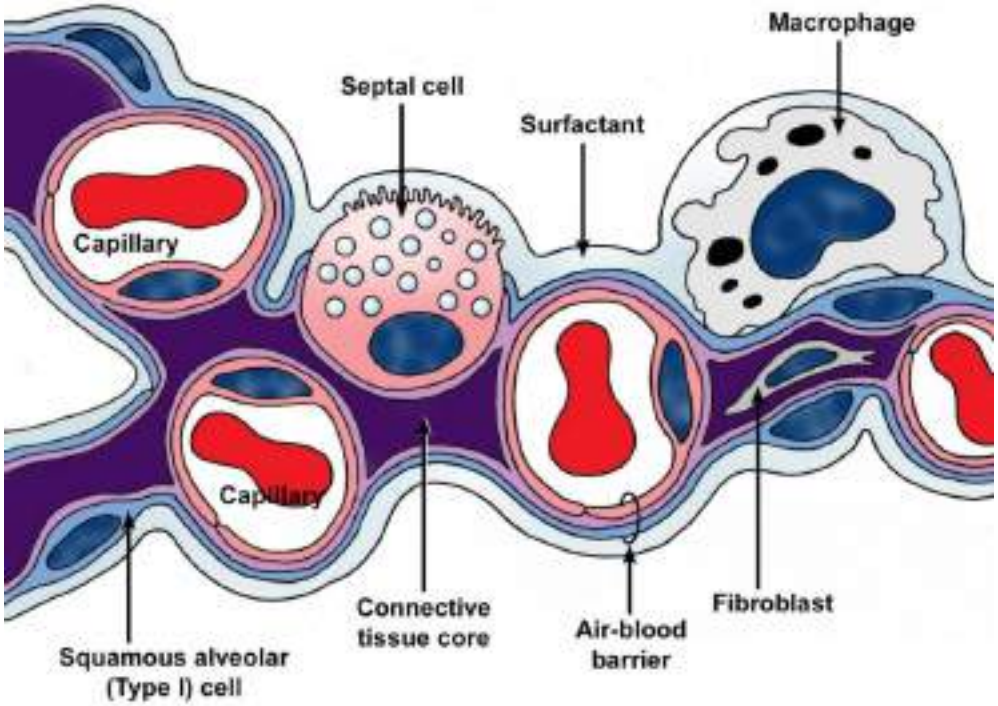

FIGURE 13.4. Components of the interalveolar septum, including the air-blood barrier.

C. Additional components

1. **Pulmonary surfactant**

a. Is an extracellular fluid coating alveolar surfaces

b. Lowers alveolar surface tension, aiding in inflation of alveoli during inspiration, and preventing collapse of alveoli during expiration

c. Is composed of a monomolecular, phospholipid surface film that covers an underlying aqueous hypophase

d. Appears during the last weeks of gestation. Absence or insufficiency of surfactant may result in respiratory distress syndrome or hyaline membrane disease in infants born prematurely.

2. **Alveolar macrophages**

a. Lie free in the alveolar space within the surfactant layer. With congestive heart failure, RBCs pass into alveolar spaces and are phagocytized by these macrophages, which are then called "heart failure" cells.

b. Are located within the connective tissues of all respiratory passageways. Macrophages that engulf dust and carbon particles are called dust cells.

3. **Alveolar or Kohn's pores**. Small openings in the interalveolar septa between neighboring alveoli that aid in equalizing interalveolar pressure. These pores can contribute to the spread of bacteria in the lung.

AIR-BLOOD BARRIER

I. The **air-blood barrier** separates air from blood. Oxygen and carbon dioxide must cross this barrier during gas exchange.

II. Composition

A. Squamous alveolar (type I) cell with its basal lamina

B. Capillary endothelial cell with its basal lamina

C. In most cases the basal laminae are fused.

PLEURA *(images)*

I. The **pleura** is a serous membrane (serosa) that lines each thoracic cavity and is reflected over the exterior surface of each lung.

II. Composition

A. Simple squamous epithelium **(mesothelium)**

B. Underlying connective tissue layer with elastic fibers

III. Produces a fluid film that lubricates the surface of the lungs and provides surface tension for lung expansion

IV. Components

A. **Visceral pleura**. Pleura reflected over the surface of the lung

B. **Parietal pleura**. Pleura reflected onto the inner body wall

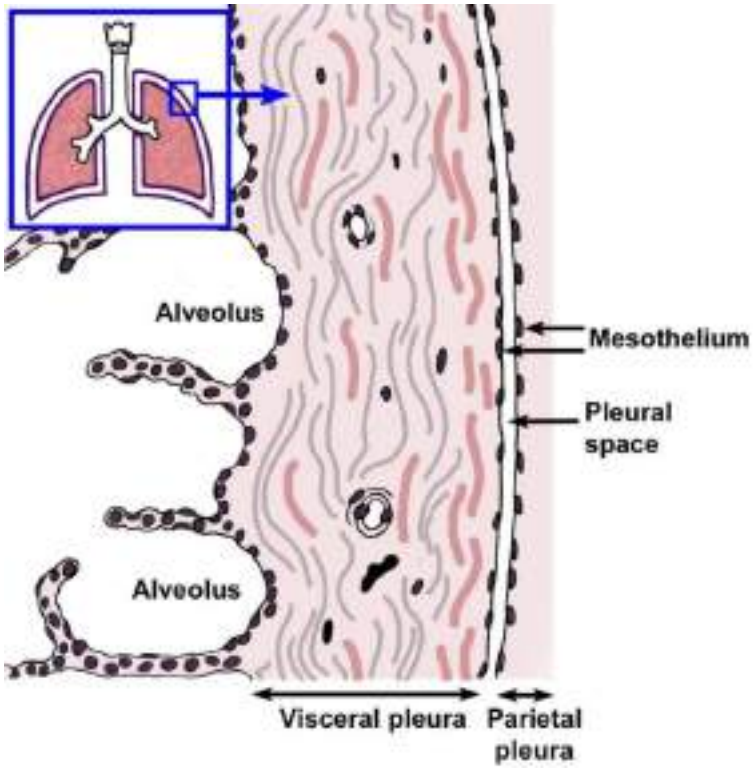

Figure 13.5 Pleura

VASCULAR SUPPLY TO LUNG *(images)*

I. Pulmonary circulation supplies deoxygenated blood for gas exchange

A. The **pulmonary artery** and its branches travel adjacent to the bronchial passageways, supplying deoxygenated blood to the pulmonary capillaries. Pulmonary arteries are comparable in diameter to their neighboring

respiratory passageways.

B. **Alveolar (pulmonary) capillaries** lie in the interalveolar septa, forming part of the air-blood barrier. These abundant capillaries anastomose to form pulmonary veins.

C. **Pulmonary veins** carry oxygenated blood, and travel alone in the parenchyma away from respiratory passageways. After leaving a lung lobule, pulmonary veins, the bronchial passageways, and pulmonary arteries collect near the hilum of the lung.

II. **Bronchial circulation** supplies oxygenated blood and nutrients to the tissue layers forming the walls of the bronchial passageways. These vessels, therefore, lie within and are much smaller than the wall of the passageways they supply.

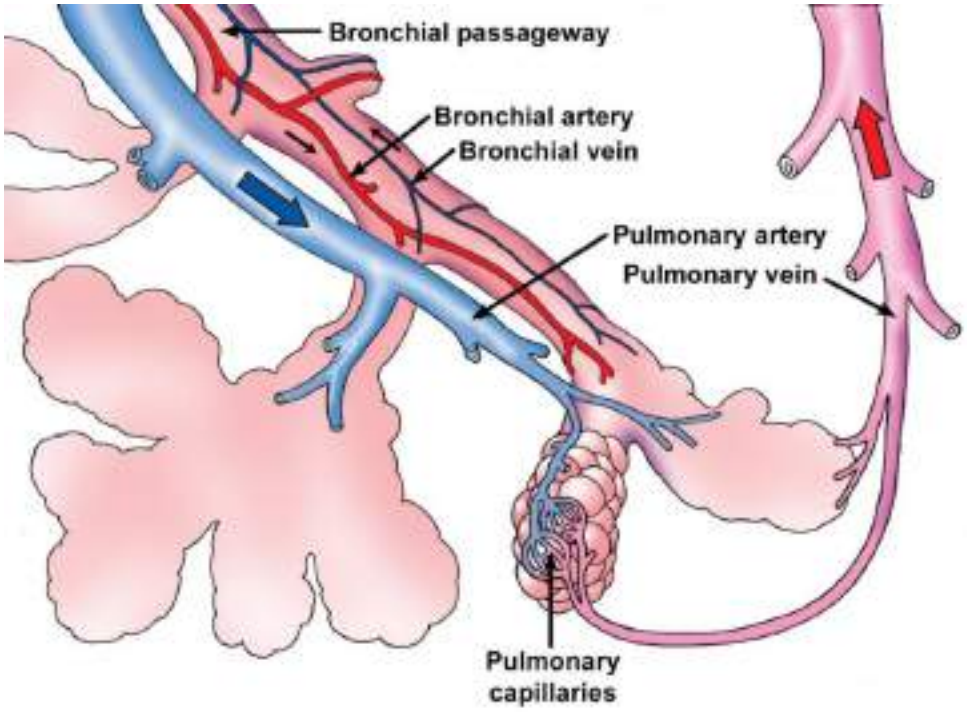

FIGURE 13.6. Vascular supply to the lungs. Arrows indicate direction of blood flow.

CHAPTER 11

SKIN (INTEGUMENTARY SYSTEM)

FUNCTIONS OF SKIN

I. Protection against physical abrasion, chemical irritants, pathogens, UV radiation, and desiccation

II. Thermoregulation

III. Reception of pressure and touch sensations

IV. Production of vitamin D

V. Excretion

COMPONENTS OF SKIN

I. **Epidermis**. Stratified squamous keratinized epithelium

II. **Dermis**. Composed of two layers of connective tissue containing blood vessels, nerves, sensory receptors, and sweat and sebaceous glands. Beneath the dermis is a layer of loose connective and adipose tissues that forms the superficial fascia of gross anatomy termed the **hypodermis (subcutis)**. This layer is considered along with the skin, though technically it is not part of the integument.

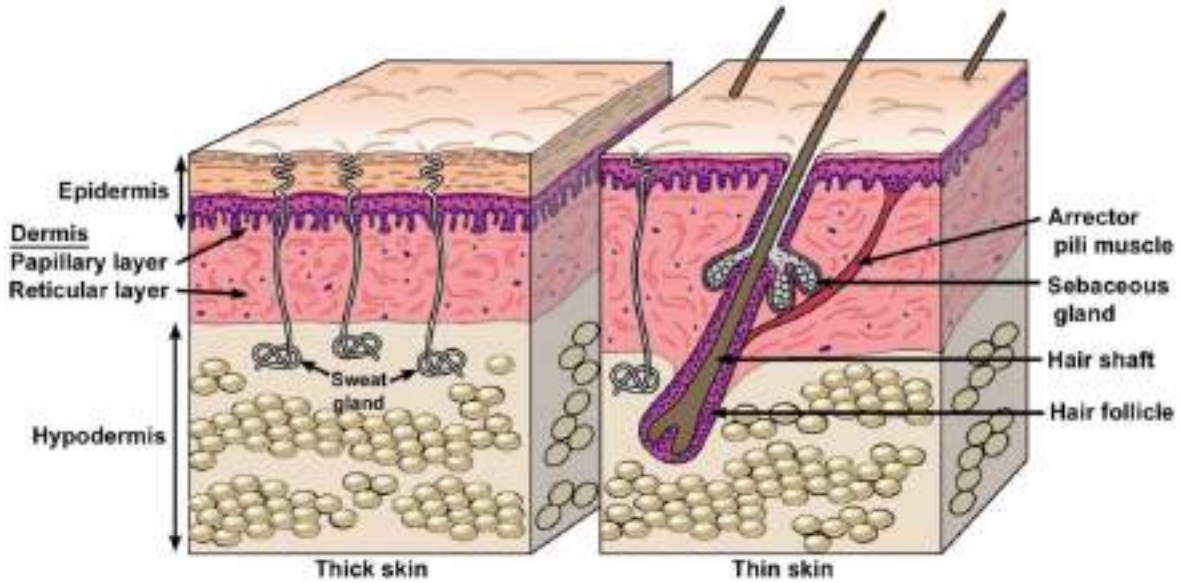

FIGURE 11.1. Structure of thin and thick skin.

CLASSIFICATION OF SKIN (Based on the thickness of the epidermis)

I. **Thin skin**

A. Covers entire body except palms and soles; 0.5 mm thick on the eyelid, 5 mm thick on the back and shoulders

B. Epidermis is thin, 0.075-0.15 mm thick, but the dermis varies from thin to very thick, depending on location.

C. Possesses hair with sebaceous glands

D. Sweat glands are present.

II. **Thick (glabrous) skin**

A. Located on palms of the hands and soles of the feet; 0.8-1.5 mm thick

B. Epidermis is 0.4-0.6 mm thick.

C. Hairless and, thus, possesses no sebaceous glands

D. Sweat glands are present.

EPIDERMIS *(images)*

I. Cell types

A. **Keratinocytes**. Keratinizing epidermal cells, major cell type in the epidermis

B. **Melanocytes**. Melanin pigment-producing cells

1. Present in stratum germinativum and stratum spinosum

2. Rounded cell bodies with clear cytoplasm. Numerous "dendrite-like" processes insinuate themselves between the keratinocytes

3. Synthesize **melanin**, a dark brown pigment that is packaged into **melanosomes** and injected into keratinocytes

4. Melanin caps the keratinocyte nucleus, reducing damage from solar radiation.

C. **Langerhans cells**. Macrophages that function in immunological skin reactions.

D. Merkel's cells. Touch receptors.

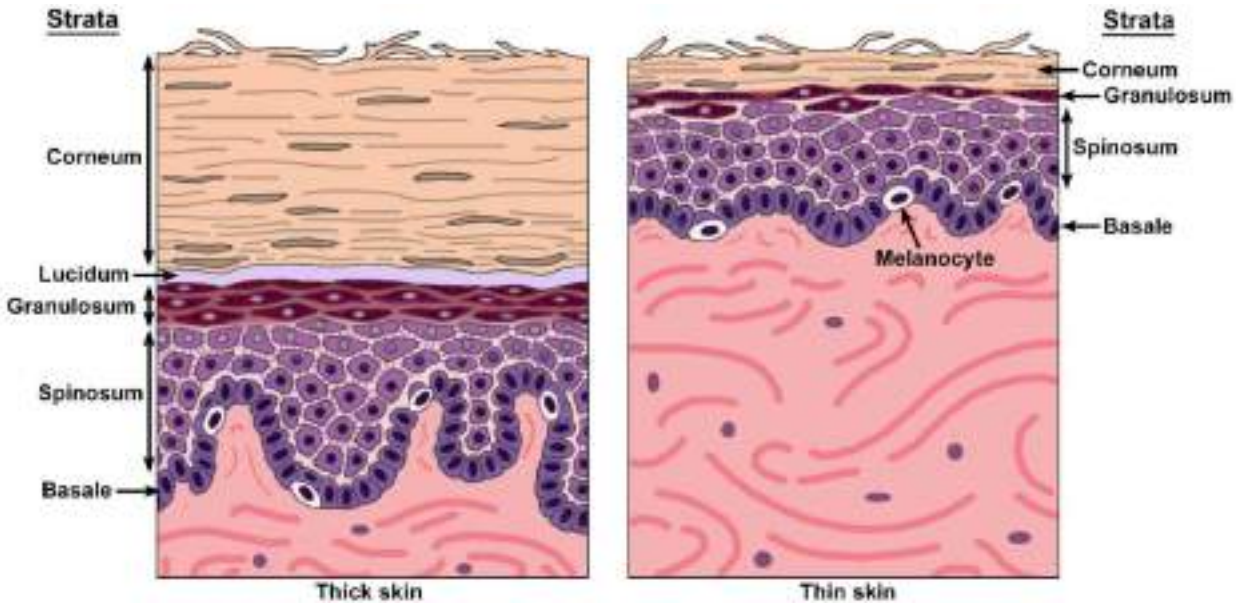

FIGURE 11.2. Comparison of epidermal layers in thick and thin skin.

II. Layers of the epidermis and keratinization

A. The epidermis is a stratified squamous, keratinized (dry) epithelium. It is continually renewed every 15-30 days. Rapid cell proliferation occurs primarily in the deepest layer (stratum germinativum) and daughter cells differentiate as they migrate toward the surface. This differentiation involves a process called keratinization, which results in a variably thick layer of nonliving cellular husks at the surface of the epidermis. All cells in the epidermis that undergo the keratinization process are called keratinocytes.

B. Layers of the epidermis

1. **Stratum basale (germinativum)**. A single layer of cuboidal to columnar shaped cells that rest on the basement membrane and undergo rapid cell proliferation. These cells contain intermediate filaments composed of keratin (tonofilaments).

2. **Stratum spinosum**. "Prickle-cell" or spiny cell layer; 3-10 cells thick. This layer is so-called because the cells are attached to one another by desmosomes, and the cellular shrinkage resulting from fixation produces the spine-like structures. These cells accumulate bundles of tonofilaments called tonofibrils.

3. **Stratum granulosum**: two to four cells thick; cells synthesize basophilic, **keratohyalin granules**, which associate with the tonofibrils. Cells also accumulate **lamellar bodies**, which contain a lipid material that is

secreted and serves as a sealant and penetration barrier between cells. Cells also begin to lose other organelles.

4. **Stratum lucidum**. A clear layer of non-nucleated, flattened cells that is only visible as a distinct layer in thick skin. In this region, the proteins contained in the keratohyalin granules mediate the aggregation of tonofibrils. This process occurs whether or not a distinct stratum lucidum is visible.

5. **Stratum corneum**. Variably thick layer of extremely flattened, cornified scales containing aggregated tonofibrils surrounded by a thickened plasma membrane. These cell remnants are sloughed off without damage to the underlying, living epidermal cells.

III. Epidermal-dermal junction

A. Scalloped margin at the interface of the epidermis and dermis, formed by interdigitations of:

1. **Epidermal pegs**. Downward projections of the epidermis

2. **Dermal papillae**. Upward, finger-like protrusion of connective tissue from the dermis

B. This junction strengthens the attachment of the epidermis to the underlying dermis.

DERMIS *(images)*

I. Composition

A. **Papillary layer**

1. Located immediately beneath the basement membrane of the epidermis, forming the dermal papillae

2. Thin layer composed of loose connective tissue

3. Contains small blood vessels, nerves, lymphatics, and the sensory receptors, Meissner's corpuscles

B. **Reticular layer**

1. Located between the papillary layer and the hypodermis

2. Thick layer composed of dense, irregular connective tissue

3. Contains larger nerves and blood vessels, glands, hair follicles, and the

sensory receptors, Pacinian corpuscles and Ruffini end organs

II. Vasculature of the dermis

A. **Papillary plexus** located in the dermal papillae

B. **Cutaneous plexus** located in the reticular layer of the dermis

C. **Arteriovenous anastomoses** allow shunting of blood between papillary and cutaneous plexuses for temperature regulation.

HYPODERMIS (SUBCUTIS)

I. Not technically part of the integument

II. Composed of loose connective tissue and adipose tissue, which can accumulate in large fatty deposits

III. Provides anchorage for skin to the underlying tissues

IV. May contain the bases of sweat glands and hair follicles

V. Many sensory receptors, especially Pacinian corpuscles, are present.

STRUCTURES ASSOCIATED WITH THE SKIN

I. Glands ***(images)***

A. **Sweat glands**

1. Simple, coiled tubular glands

2. Contain **myoepithelial cells**, which are specialized cells that contract to aid in the expulsion of the sweat

3. Types of sweat glands

a. **Merocrine or eccrine**. Located in all regions of the body except the axillary and anal regions; produce a watery secretion that empties onto the surface of the epidermis

b. **Apocrine**. Restricted to the axillary, areolar, and anal regions; much larger than eccrine sweat glands with a broader lumen. Produce a viscous secretion that empties into the hair follicle. Do not secrete by the apocrine mode, as once thought.

B. **Sebaceous glands**

1. Simple, branched acinar glands

2. Usually secrete into a hair follicle

3. Produce sebum, an oily secretory product, released by the holocrine mode of secretion

4. Absent from thick skin

II. **Hair follicles**

A. Invaginations of the epidermis

B. Consist of a **bulb** at the base of the follicle that is located in the hypodermis or in the deep layers of the dermis. **Internal and external sheaths** surround the growing **hair shaft** as it passes though the dermis and epidermis.

C. An **arrector pili** muscle attaches a hair follicle to the papillary layer of the dermis. Contraction provides elevation of the hair, forming "goose-bumps."

III. **Nails *(images)***

A. Keratinized epithelial cells on the dorsal surface of the fingers and toes

B. Consist of a **nail plate** that corresponds to the stratum corneum of the epidermis. This plate rests on the **nail bed**, consisting of cells corresponding to the stratum spinosum and stratum germinativum.

C. **Nail root** lies in an epidermal fold, whose stratum corneum forms the **eponychium (cuticle)**

D. **Nail matrix** lies beneath the nail root and is the germinative portion of the nail.

E. The **hyponychium**, a thickened epidermis, secures the nail at the fingertip

IV. Sensory structures ***(images)***

A. Nonencapsulated. **Free nerve endings** in the epidermis, responsive to touch, pressure, heat, cold, and pain

B. Encapsulated pressure receptors

1. **Meissner's corpuscle**

a. Located at the apex of a dermal papilla

b. Consists of a coil of **Schwann cells** around a nerve terminal

c. Responds to light touch

2. **Pacinian corpuscle**

   a. Located in the dermis and hypodermis

   b. Consists of concentric layers of **endoneurial cells** around a nerve terminal

   c. Responds to vibration and deep pressure

3. **Ruffini ending**

   a. Located in the dermis

   b. Consists of groups of nerve terminals surrounded by a thin connective tissue capsule

   c. Responds to touch and pressure

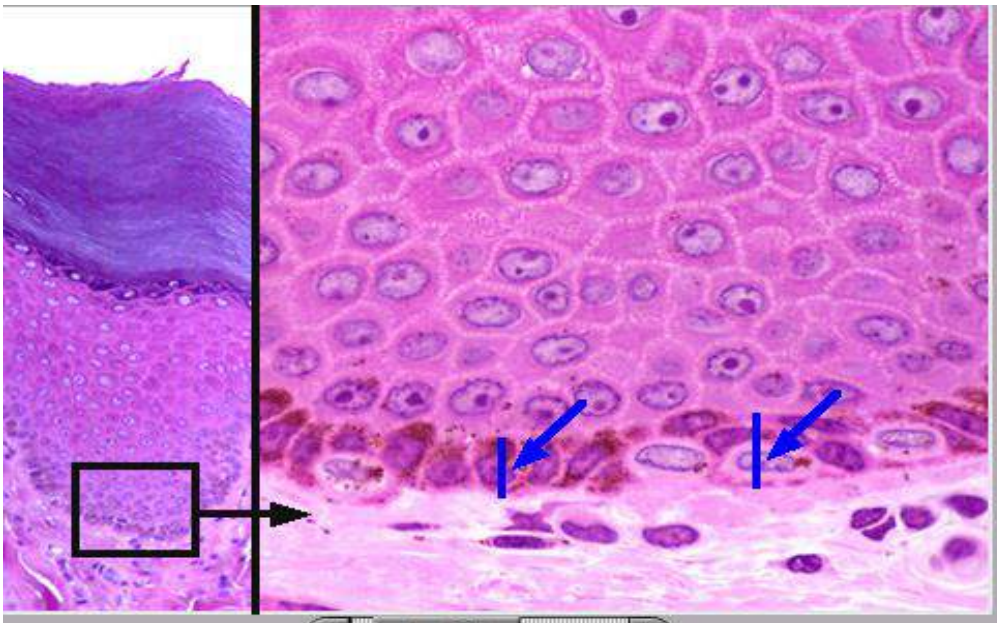
spinosum

4 of 19

Stratum basale -- Stratum basale (germinativum) is the deepest layer of the epidermis and rests directly on the basal lamina. Cell division occurs primarily in the stratum basale, forming daughter cells which undergo keratinization while moving up to form the more superficial layers. Stratum basale is composed primarily of keratinocytes. 200x, 1000x

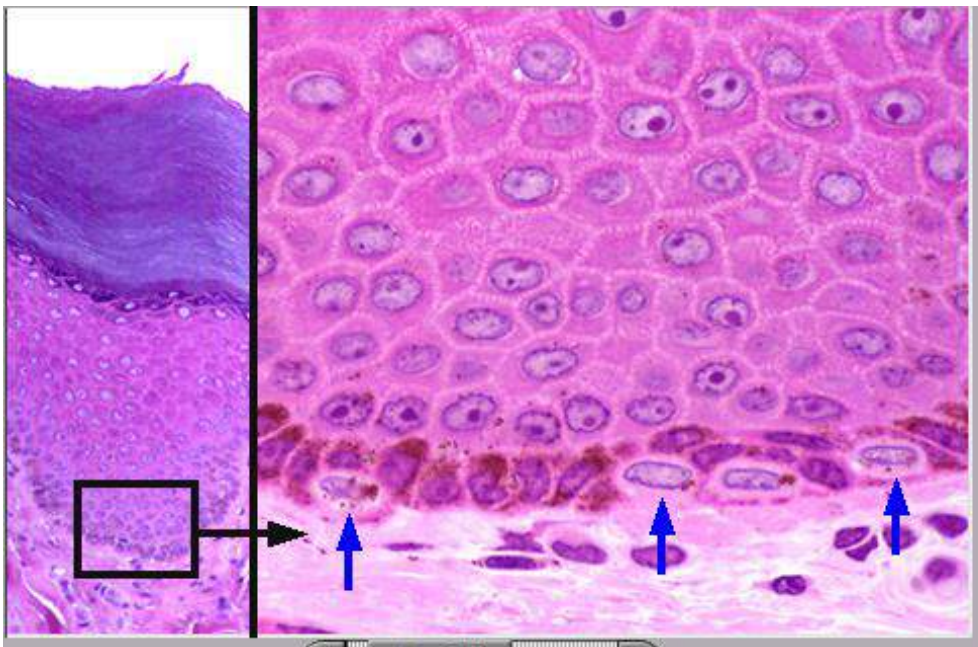


click to identify:

› Stratum basale >
Melanocytes >
Melanin granules
Stratum >
spinosum

4 of 19

The stratum basale consists of a single layer of cuboidal to columnar shaped cells and rests on the basement of the epidermis. These cells accumulate melanin granules which are synthesized by neighboring melanocytes. The majority of keratinocyte proliferation occurs in stratum basale.



click to identify:

Stratum basale >
› Melanocytes >
Melanin granules
Stratum > spinosum

4 of 19

Melanocytes are located primarily in the stratum germinativum, although they can also be found in the stratum spinosum. Melanocytes synthesize melanin pigment, which they package into melanosomes (melanin granules) that are transferred to neighboring keratinocytes. Melanin protects nuclear DNA in keratinocytes against ultraviolet light.

14 of 19

Stratum granulosum -- The stratum granulosum is three to five cell layers thick with prominent, basophilic, keratohyalin granules. These granules combine with the tonofilaments (keratin intermediate filaments) to produce keratin. At the same time, the organelles in these cells degenerate, resulting in keratinized scales which form the stratum corneum. 200x, 1000x

14 of 19

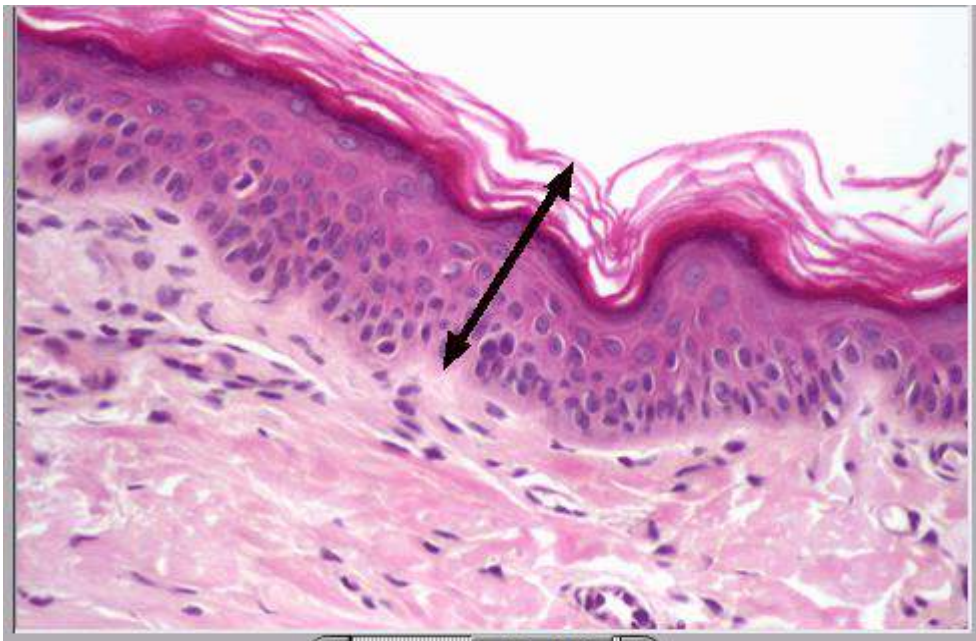
As the keratohyalin granules combine with the tonofilaments, the nuclei and organelles in the cells degenerate, resulting in keratinized scales which form the stratum corneum.



18 of 19

Stratum corneum -- Stratum corneum consists of squamous cells containing keratin protein surrounded by a thickened plasma membrane. These cells are continuously shed from the surface of the epidermis and are replenished through the upward migration and ongoing keratinization of epidermal keratinocytes. Stratum lucidum does not form a discrete layer in thin skin, as seen here. 400x

Each sweat gland possesses a long, unbranched duct which passes through the dermis, interconnecting the secretory tubules with the surface of the skin. The portion of the duct adjacent to the secretory unit of the gland coils with the secretory part similar to winding yarn into a ball.

Apocrine sweat gland
6 of 11
Apocrine sweat gland -- Apocrine sweat glands are located in the axillary, areolar and anal regions. Contary to their name, they secrete a thick, protein-rich secretion by the merocrine mode. These secretions acquire a distinctive odor by the action of bacteria on the skin surface. The duct of an apocrine sweat gland empties into the hair follicle. 400x

The third cell type is the contractile myoepithelial cell, whose long extensions wrap around the tubule. These epithelial cells possess contractile filaments and are located at the periphery of the tubule within the basement membrane. Their contractions assist in expulsion of the gland contents. Myoepithelial cells are also present in mammary glands, which are modified sweat glands

Sebaceous gland -- Sebaceous glands secrete by the holocrine mode. Cells at the periphery proliferate and, as they are pushed toward the center of the acinus, accumulate lipid (sebum) and degenerate, eventually filling the center of the acinus. These dead cells, and the sebum they contain, are released into a short duct opening onto the hair shaft. 400x

CHAPTER
5

Supporting Connective Tissues

Cartilage

General Concepts

I. Composition is similar to that of all connective tissues.
   A. *Cells*.
   B. *Extracellular matrix* consisting of fibers and ground substance.
II. Cartilage is avascular and possesses no lymph vessels or nerves.
III. Types of cartilage
   A. Hyaline. Provides nonrigid support.
   B. Elastic. Provides support with large amount of flexibility.
   C. Fibrocartilage. Provides strength in areas under stress.

Components of Cartilage

I. *Perichondrium*. Layer of connective tissue proper surrounding cartilage tissue. Layers include
   A. *Fibrous layer.* Outer portion, composed of dense connective tissue, serves as a source of reserve cells for the chondrogenic layer.
   B. *Chondrogenic layer.* Inner, more cellular portion contains chondroblasts and blends imperceptibly into cartilage tissue proper.

Digital Histology: An Interactive CD Atlas with Review Text, Second Edition
By Alice Swope Pakurar and John W. Bigbee

II. Cells
   A. *Chondroblasts*
      1. Lie on the surface of cartilage in the chondrogenic layer of perichondrium.
      2. Secrete extracellular matrix around themselves, thereby becoming chondrocytes.
   B. *Chondrocytes*
      1. Are chondroblasts that have surrounded themselves with matrix.
      2. Lie within cartilage in potential spaces called lacunae.
      3. Secrete and maintain extracellular matrix.
      4. Frequently form *isogenous groups*, a cluster of chondrocytes, resulting from the proliferation of a single chondrocyte.

III. *Extracellular matrix*. Both flexible and noncompressible.
   A. Composition
      1. *Fibers.* Collagen fibrils and fibers predominate in hyaline cartilage and fibrocartilage, respectively; elastic fibers predominate in elastic cartilage.
      2. *Ground substance.* Tissue fluid surrounds proteoglycan aggregates bound to collagen fibrils by electrostatic interactions. Collectively, these form a firm gel, which resists compressive forces.
   B. Subdivisions
      1. *Territorial matrix* immediately surrounds chondrocytes. This matrix stains more intensely with hematoxylin due to the high concentration of proteoglycans.
      2. *Interterritorial matrix* is the lighter-staining matrix outside the territorial matrix and between isogenous groups.

GROWTH OF CARTILAGE

I. *Appositional* growth occurs at the surface of cartilage. New cartilage is added (apposed) to the surface of preexisting cartilage by the activity of chondroblasts lying in the chondrogenic layer of the perichondrium.

II. *Interstitial* growth occurs from within cartilage tissue. Chondrocytes produce additional matrix and divide, forming isogenous groups.

TYPES OF CARTILAGE

I. *Hyaline cartilage*
   A. Is the most common cartilage type and is hyaline (glassy) in appearance.
   B. Contains type II collagen. Because of the small size of these fibrils and because they have the same refractive index as ground substance, they are not visible with the light microscope by conventional staining methods.
   C. Stains blue with conventional dyes, due to the relative abundance of its ground substance matrix.
   D. Possesses numerous isogenous groups.
   E. Function and distribution. Forms most of the cartilages of the body, comprises the fetal skeleton, attaches ribs to the sternum, forms epiphyseal plates, and lines articular surfaces. (The lack of a perichondrium on the articular cartilages provides a smooth, glassy articular surface.)

II. *Elastic cartilage*
   A. Has a visible network of interlacing elastic fibers in addition to collagen type II.
   B. Possesses fewer isogenous groups than does hyaline cartilage.
   C. Function and distribution. Pinna of ear, epiglottis, smaller laryngeal cartilages (i.e., present where flexibility and support are necessary).

III. *Fibrocartilage*
   A. Is a functional and structural intermediate between hyaline cartilage and dense connective tissue.
   B. Possesses abundant collagen type I fibers, arranged in either a regular or an irregular configuration. These collagen fibers cause this cartilage to stain pink with eosin.
   C. Has minimal ground substance. The ground substance that is present is usually located immediately around the chondrocytes.
   D. Possesses few isogenous groups.
   E. Combines great tensile strength with flexibility.
      1. Frequently found where a tendon or a ligament attaches to a bone (regular arrangement of fibers).
      2. Located in the pubic symphysis and knee cartilages (irregular fiber arrangement).

REGRESSIVE CHANGES IN CARTILAGE

I. Occur in cartilage more frequently than in many other tissues.
II. Regressive changes also occur in the hyaline cartilage of the epiphyseal plate and represent critical steps in endochondral bone formation.
III. Stages of regression
    A. Chondrocytes hypertrophy and secrete alkaline phosphatase that provides a calcifiable matrix.
    B. Calcium phosphate is deposited in the matrix, prohibiting diffusion of nutrients to the chondrocytes.
    C. Chondrocytes die, leaving behind empty lacunae and the calcified matrix.

SUPPORTING CONNECTIVE TISSUES: BONE

GENERAL CONCEPTS

I. Bone
    A. Provides structural support, giving shape and form to the body.
    B. Enables movement through the action of muscles inserting on the bone.
    C. Serves as a stored source for calcium and phosphate.
    D. Contains bone marrow (myeloid tissue).

II. Histological preparation of bone
   A. *Ground bone preparation*. Unpreserved bone is ground to a thinness where light can be transmitted through it. Because no preservation has occurred, neither cells nor organic matrix survives. Lamellae, lacunae, canaliculi, and general architecture of inorganic matrix are well displayed.
   B. *Decalcified bone*. Cells are fixed (preserved) and inorganic matrix removed by decalcification. Good detail of organic matrix (cells, periosteum, etc.) is maintained, but lamellae and inorganic matrix are difficult to distinguish.

Gross Appearance of Bone, Macroscopic Structure

I. *Compact bone.* Appears as a solid mass to the naked eye, covering the exterior of bones and forming the shaft of long bones.
II. *Spongy or cancellous bone.* Gross appearance is like a sponge, with a labyrinth of bony spicules and intervening spaces that are filled with loose connective tissue or red marrow and blood vessels. Spongy bone is located in the interior of bones.

Architecture of a Long Bone

I. The *diaphysis* (shaft), composed of compact bone, is hollow, is usually lined by a thin band of spongy bone, and is filled with yellow marrow in the adult.
II. An *epiphysis*, the knob at either end of the diaphysis, is composed of a thin rim of compact bone. The spongy bone in its interior houses red marrow.
III. *Metaphysis*. Flared region between diaphysis and epiphysis.
IV. *Epiphyseal plate*. Hyaline cartilage separating epiphysis and metaphysis in growing bones. Growth in bone length occurs as hyaline cartilage in the epiphyseal plate goes through various stages of regression, providing a framework on which bone is deposited. When the hyaline cartilage in the epiphyseal plate is exhausted, growth stops. The epiphysis and metaphysis fuse in the adult, leaving an epiphyseal line as a remnant of the epiphyseal plate.

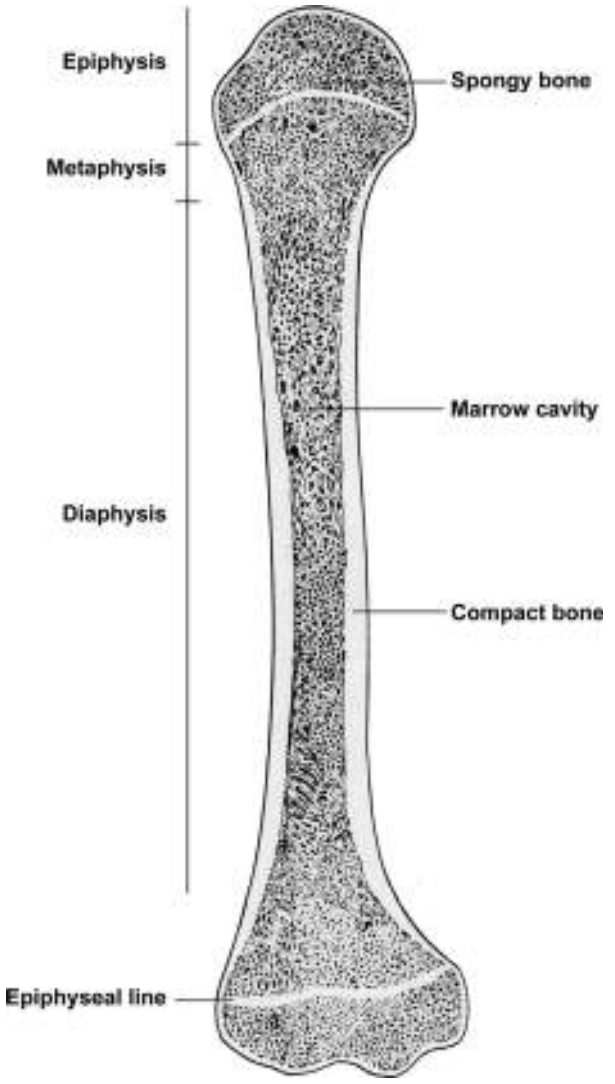

FIGURE 5.1. Longitudinal section of an adult long bone.

V. Marrow

A. *Red marrow,* found in all bones of the fetus, is restricted to spongy bone areas of selected bones in the adult and contains hemopoietic tissue that forms blood cells.

B. *Yellow marrow,* found in the shafts of long bones in the adult, consists mainly of adipose connective tissue that retains the potential to become red marrow under hemorrhagic stress.

VI. *Articular cartilage* is composed of hyaline cartilage and covers articular surfaces of bone. This cartilage does not possess a perichondrium; the glassy, smooth cartilage provides a good articulating surface.

Components of Bone

I. *Extracellular matrix*
   A. *Organic portion, osteoid.* Secreted by osteoblasts
      1. Collagen type I *fibers* comprise the majority of the organic matrix. Their predominance causes bone to stain pink with eosin.
      2. *Ground substance* is minimal, composed of glycosaminoglycans such as chondroitin sulfate, keratan sulfate, and some glycoproteins that avidly bind calcium.
   B. *Inorganic portion.* Calcium and phosphate, in the form of hydroxyapatite crystals, are deposited along the collagen fibrils and form 50% of the dry weight of bone. This ossified matrix renders bone impermeable to diffusion of nutrients and requires that bone be well vascularized.

II. Cells
   A. *Osteoblasts*
      1. Located on all exterior surfaces of bone as the innermost portion of the periosteum or in the endosteum lining all interior bony surfaces.
         a. Inactive osteoblasts are flattened cells with heterochromatic nuclei.
         b. Active osteoblasts are stellate and contain organelles necessary for protein, primarily collagen, production. These cells synthesize high levels of alkaline phosphatase.
      2. Function to synthesize bone
         a. Secrete osteoid first.
         b. In the presence of alkaline phosphatase, osteoblasts facilitate the deposition of calcium phosphate, thus mineralizing the osteoid.
   B. *Osteocytes*
      1. Are osteoblasts that have completely surrounded themselves by bony matrix and, therefore, must lie within, rather than on, bone tissue. These flattened, inactive cells lie in *lacunae* (spaces) in the bone and extend long processes from the cell body. These processes

lie in narrow bony tunnels called *canaliculi* and connect, via gap junctions, with adjacent osteocytes and/or osteoblasts at the bone surface.

2. Function to transport materials between blood and bone and to maintain surrounding matrix; they do not divide or secrete matrix.

C. *Osteoclasts*

1. Are large cells with 15–20 or more nuclei and vacuolated, frothy cytoplasm. A ruffled border, the highly enfolded cell membrane facing the bone, is the site of bone resorption.
2. Are located on internal surfaces as part of the endosteum or on external surfaces as part of the osteogenic layer of the periosteum. Osteoclasts lie in depressions in the bone, *Howship's lacunae*, which form as osteoclasts resorb bone.
3. Resorb bone via the acid phosphatase and proteolytic enzymes they secrete.

III. Surface coverings

A. *Periosteum*. Double layer of connective tissue surrounding the outer surface of bones, except for articular surfaces.

1. Layers
   a. *Fibrous layer*. Outer layer of dense connective tissue that serves as a reserve cell source for the osteogenic layer.
   b. *Osteogenic layer*. Inner, more cellular layer, contains osteoblasts, osteoclasts, and/or osteoprogenitor cells. Site of bone deposition and resorption.
2. Well vascularized and richly innervated.

B. *Endosteum*

1. Is composed of a single row of osteoblasts, osteoclasts, and/or osteoprogenitor cells that line all interior surfaces of bone except for lacunae and canaliculi.
2. Serves as a means of bone growth and/or resorption.

MICROSCOPIC APPEARANCE OF BONE (RELATED TO THE AGE OF A BONE)

I. *Woven* or *immature bone* is the first bone deposited.

A. May be either spongy or compact.

B. Referred to as woven bone because fibers are deposited in a random array.
C. Contains osteocytes that are more numerous and spherical than those of lamellar bone. These osteocytes are not in any orderly arrangement.
D. Is less well mineralized than lamellar bone and, therefore, appears bluer than lamellar bone with hematoxylin and eosin stains.
E. Is usually resorbed and replaced by lamellar bone.

II. *Lamellar* or *mature bone*
A. Replaces most woven bone or may be deposited *de novo*.
B. May be either spongy or compact.
C. Is referred to as lamellar bone because the matrix is deposited in layers or lamellae.
D. Fibers are deposited in parallel array within a lamella.
E. Osteocytes are fewer and flatter than those in woven bone and are organized in rows between the lamellae.
F. Better mineralized than woven bone.
G. Bone is not a static structure and is constantly being resorbed and reconstructed. Therefore, lamellar bone is also resorbed and reconstructed throughout life.

Architecture of Adult, Compact Lamellar Bone

I. *Outer circumferential lamellae*. Stacks of lamellae extend at least partially around the outer circumference of a long bone. Deposition of these lamellae by the periosteum results in increased thickness in the wall of the diaphysis.
II. *Inner circumferential lamellae*. Stacks of lamellae extend at least partially around the inner circumference of a long bone facing the marrow cavity. Deposition of these lamellae by the endosteum results in increased thickness of the wall of the diaphysis.
III. *Haversian systems, osteons*
A. Primary structures of compact lamellar bone.
B. Cylinders of concentric lamellae, deposited by endosteum, that run parallel to the long axis of a bone.
C. Composition

1. Central *Haversian canal*
   a. Appears round in cross-section with a smooth periphery.
   b. Contains a blood vessel(s) and loose connective tissue.
   c. Is lined with an endosteum.
2. Concentric lamellae (4–20) surround the Haversian canal
   a. Collagen fibers are in parallel alignment within a single lamella, wrapping helically around the Haversian canal.
   b. Pitch of the helix varies with each lamella in the osteon.

D. Provides great strength to a long bone.

E. An osteon is formed by the centripetal deposition of the concentric lamella (i.e., outer lamella is the oldest).

IV. Additional lamellae/structures associated with adult, compact lamellar bone

A. *Interstitial lamellae.* Portions of Haversian systems that remain after resorption of the rest of the osteon. These lamellae are interposed between other, complete Haversian systems.

B. *Volkmann's canals.* Channels oriented perpendicularly between adjacent Haversian canals, interconnecting these canals with each other and with the surfaces of bone. Volkmann's canals contain blood vessels that transport blood from the surface of bone to blood vessels within Haversian canals.

C. *Cement lines.* Thin, refractive lines that are collagen poor and stain, therefore, with hematoxylin. Cement lines are located
   1. Around Haversian systems, demarcating where resorption stopped and the formation of a new osteon began.
   2. Beneath and between circumferential lamellae, denoting where deposition of lamellae halted for a period of time and then began again.

BONE GROWTH, DEPOSITION, AND RESORPTION

BONE GROWTH

I. New, adult bone is always laid down on preexisting bone or cartilage.

II. Bone growth is always appositional, with either endosteum or periosteum laying down lamellae of bone. Interstitial growth is impossible in bone

because its rigid, ossified matrix does not allow osteocytes to secrete additional matrix or to divide.

Bone Deposition

I. Newly deposited bone assumes the shape of the bone or cartilage on which it is deposited.
II. In spongy, lamellar bone, new lamellae are laid down by osteoblasts in the endosteum located at the periphery of each trabecula, thus increasing its thickness.
III. In compact lamellar bone, new lamellae are laid down either as outer circumferential lamellae by osteoblasts in the periosteum or as inner circumferential lamellae and Haversian systems (osteons) by the endosteum.

Bone Resorption

I. Definition. Removal of bone by osteoclasts for remodeling during growth and/or to mobilize calcium throughout life.
II. Resorption process
    A. Osteoclasts on the periosteal and endosteal surfaces resorb bone from bone surfaces.
    B. *Resorption canal*
        1. Is a cylindrical, longitudinal tunnel formed as compact bone in the interior of bone is resorbed.
        2. Appears in cross-section as an irregularly shaped, bony surface lined with an endosteum containing osteoclasts.
        3. Usually extends past cement lines, eroding through portions of several osteons. Therefore, remnants of resorbed osteons may surround the resorption canal.
        4. Is not lined by concentric lamellae as are osteons.
        5. When resorption stops, osteoblasts begin filling in a resorption canal by centripetal (from outside to inside) deposition of new lamellae, forming a new osteon. The newest lamella of this secondary osteon is the one adjacent to the Haversian canal.
        6. Remains of partially resorbed Haversian systems around this secondary osteon are called interstitial lamellae.

BONE FORMATION (OSSIFICATION)

INTRAMEMBRANOUS BONE FORMATION

I. Definition. Bone formation by a connective tissue membrane. No cartilage precedes this bone formation. Bone formed may be woven or lamellar, spongy or compact.

II. Connective tissue membranes involved in intramembranous ossification include mesenchyme in the fetus and periosteum or endosteum in both the fetus and the adult.

III. Occurrence of intramembranous bones
   A. Bone laid down by mesenchyme forming the flat bones of the skull and part of the mandible.
   B. Bone laid down by the periosteum or endosteum.

IV. Types of intramembranous ossifications
   A. Ossification from mesenchyme in the fetus.
      1. Mechanism of ossification
         a. Mesenchymal cells cluster and differentiate into osteoblasts that secrete organic matrix (osteoid) around themselves. This matrix becomes mineralized, thereby forming bone.
         b. Bone formed is woven, spongy bone.
      2. Many areas of this spongy, woven bone are converted to compact, lamellar bone by the filling in of the spaces between trabeculae with osteons.
      3. Other areas of this spongy bone are not converted to compact, however, such as the spongy bone forming the diploe of flat bones of the skull.
   B. Ossification from a connective tissue membrane, such as periosteum or endosteum, both in the fetus and in the adult.
      1. Mechanism of ossification. Osteoblasts in the endosteum or in the osteogenic layer of the periosteum secrete and lay down lamellae of bone.
      2. Lamellae conform to the shape of the bone or cartilage on which they are deposited.
         a. Lamellae deposited around a cylindrical cavity within bone form an osteon.

b. Circumferential lamellae form on the inner and outer surfaces of bone from the endosteum or periosteum, respectively.
c. Endosteum adds lamellae to trabeculae of spongy bone.

Endochondral Bone Formation

I. Definition. Formation of bone by replacement of a preexisting hyaline cartilage template. The cartilage must first undergo regressive changes that produce a framework upon which bone is deposited (ossification).

II. Bones formed endochondrally include bones at the base of the skull, long bones, vertebrae, pelvis, and ribs.

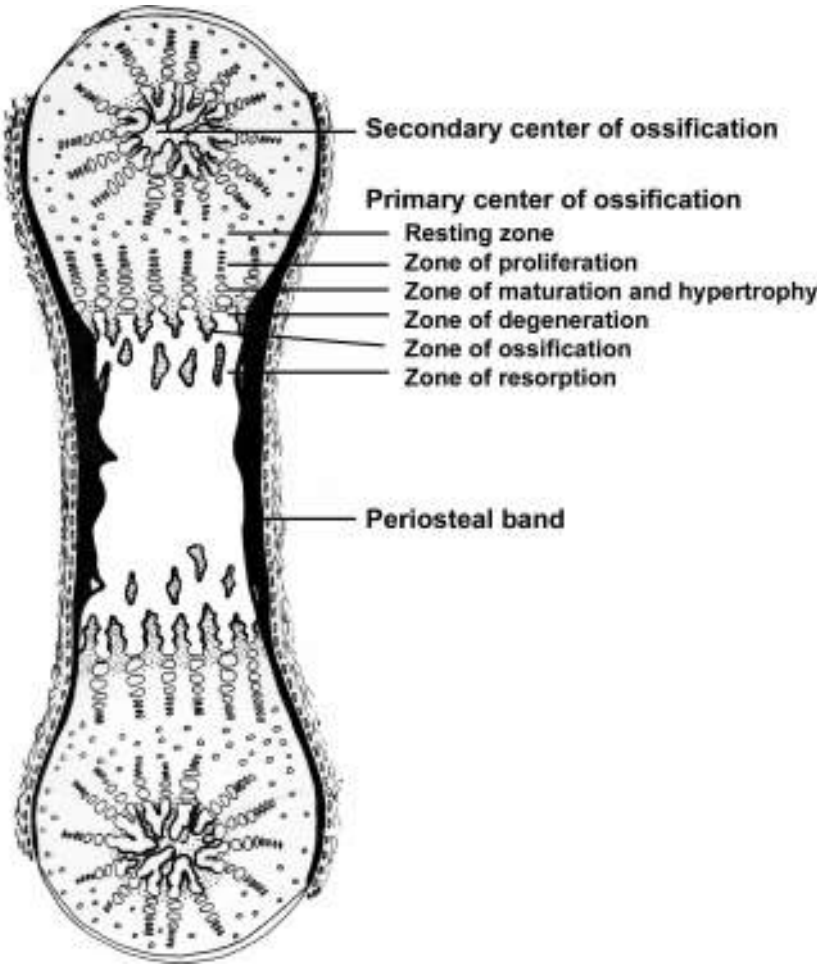

FIGURE 5.2. Zones of endochondral ossification.

III. Events occurring before ossification begins
  A. Hyaline cartilage template of the future bone is formed in the fetus. This cartilage is surrounded by a perichondrium and enlarges by appositional and interstitial growth as the fetus grows.
  B. Regressive changes begin in cartilage cells in the central, diaphyseal region of the template at what will become the primary center of ossification.
    1. Chondrocytes mature, greatly hypertrophy at the expense of surrounding matrix, and begin to secrete alkaline phosphatase.
    2. The presence of alkaline phosphatase leads to the calcification of the cartilage matrix, making it impermeable to metabolites.
    3. Chondrocytes die, leaving behind their lacunae separated by spicules of calcified cartilage matrix.
    4. The oxygen supply to the fetus is increasing as the fetal circulatory system becomes functional, supplying blood to the hyaline cartilage template of the future bone.

IV. Stages of ossification
  A. Formation of a *periosteal band* or *collar*
    1. Around the middle of the shaft of the cartilage template, the chondroblasts differentiate into osteoblasts and begin secreting a bony, rather than a cartilaginous, band called the periosteal band or collar. This cylinder of bone is formed by intramembranous ossification because it does not replace cartilage that has gone through regressive changes. The perichondrium surrounding the periosteal collar is now called a periosteum.
    2. The remainder of the cartilage template is surrounded by a perichondrium.
  B. *Primary center of ossification*
    1. One of the fetal arteries, called the *periosteal bud*, and its surrounding mesenchymal cells penetrate the diaphyseal region of the cartilage template into the area of the degenerating calcified cartilage.
    2. Mesenchymal cells accompanying the artery differentiate into osteoblasts that deposit bone on the spicules of the calcified cartilage framework. Resulting spicules consist of
      a. A core of calcified cartilage that stains blue with hematoxylin.
      b. An outer perimeter of woven bone that stains pink with eosin.

3. Some of the spicules of cartilage and bone are resorbed to form the future marrow cavity.
4. This cartilage degeneration–bone deposition process continues toward either epiphysis, becoming more organized into discrete zones, and forming the epiphyseal plate.
   a. *Resting zone* of "normal" hyaline cartilage.
   b. *Zone of proliferation* where isogenous groups of chondrocytes actively divide, forming linear isogenous groups. This zone maintains cartilage thickness.
   c. *Zone of maturation, hypertrophy, and calcification* where chondrocytes mature, hypertrophy, and produce alkaline phosphatase with the subsequent *calcification* of the cartilage matrix.
   d. *Zone of degeneration* where chondrocytes die, leaving empty lacunae surrounded by vertically oriented spicules of calcified cartilage.
   e. *Zone of ossification* where bone is deposited on the calcified cartilage spicules immediately adjacent to the bony diaphysis, thus increasing the length of that diaphysis.
   f. *Zone of resorption* where calcified cartilage–bone spicules are resorbed to form the marrow space.

C. *Secondary center of ossification* occurs in each epiphysis; ossification follows a similar pattern as that at the primary center except
   1. No periosteal band is formed.
   2. Ossification occurs in a radial manner from the original center of the secondary center of ossification.
   3. Bone resorption does not occur; thus, spongy bone permanently fills the epiphyses.
   4. Ossification does not replace articular cartilage.

V. Growth in length continues from epiphyseal plates, which
   A. Are established by formation of the primary and secondary centers of ossification.
   B. Are composed of hyaline cartilage showing the zonations described above.
   C. Are located between each epiphysis and metaphysis.
   D. Maintain a constant thickness throughout growth due to equivalent activity in the zones of proliferation and resorption.

E. Are depleted at appropriate developmental stages as cartilage proliferation stops and the epiphyseal plate can no longer perpetuate itself. Spongy bone replaces the epiphyseal plate, leaving an epiphyseal line as its remnant. This process is referred to as closure of the epiphyseal plate.

Chapter 15

URINARY SYSTEM

COMPONENTS

I. **Kidneys**. Contain the **uriniferous tubules**, which consist of nephrons and a system of collecting ducts; filter blood and produce urine

II. **Ureters**. Muscular tubes that collect urine output from the kidney and carry it to the urinary bladder

III. **Urinary bladder**. Hollow muscular organ that stores urine

IV. **Urethra**. Tube that drains urine from urinary bladder to the exterior

FUNCTIONS OF THE URINARY SYSTEM

I. Excretion of waste products of metabolism

II. Regulation and maintenance of the fluid volume of the body Regulation of acid-base balance

III. Regulation of salt concentrations and other compounds in body fluid

IV. Production of renin, an enzyme that influences blood pressure

MACROSCOPIC ORGANIZATION OF THE KIDNEY

I. **Cortex**. Broad outer zone of kidney

   A. Subdivisions

      1. **Cortical labyrinth**. "True" cortical tissue

      2. **Medullary rays**. Medullary tissue located in the cortex

   B. Contains renal corpuscles, portions of renal tubules, and collecting ducts

II. **Medulla**. Deep to cortex

   A. Subdivisions

      1. **Renal pyramids**. Inverted cones whose bases are adjacent to the cortex;

send "stripes" of medullary tissue into the cortex forming the medullary rays

2. **Renal columns**. Extensions of cortical tissue between renal pyramids

B. Consists of portions of renal tubules and collecting ducts

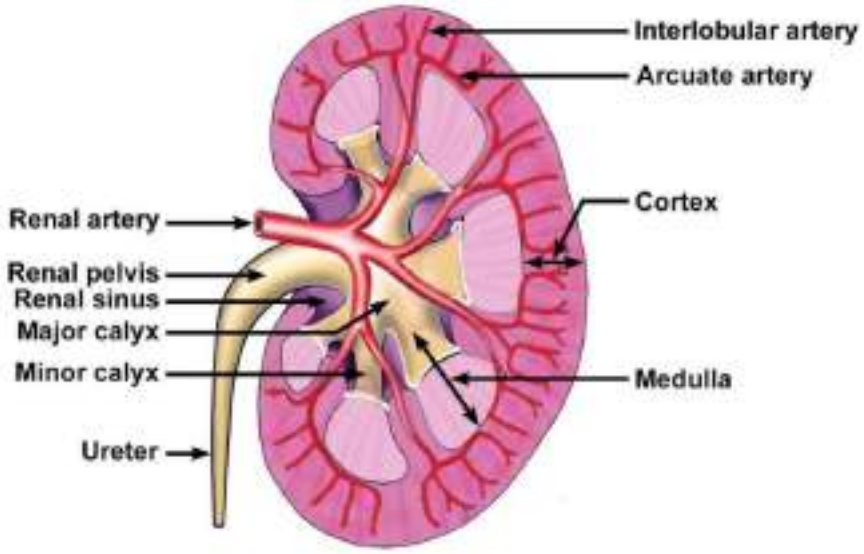

FIGURE 15.1. Extrarenal passageways and vascular supply of the kidney.

III. Renal lobulations

A. **Renal lobe**. A medullary pyramid, the surrounding renal column extending to the interlobar vessels, and the overlying cortical tissue

B. **Renal lobule**. A central medullary ray and the adjacent cortical labyrinth extending to the interlobular vessels

IV. Extrarenal passageways

A. **Minor calyx**. Funnel-shaped structure (one for each pyramid) into which the point (apex) of a pyramid projects; urine flows from the pyramid into a minor calyx and several minor calyces unite to form a major calyx.

B. **Major calyx**. Four or five per kidney; formed by the confluence of minor calyces

C. **Renal pelvis**. Structure formed by the uniting of the major calyces; forms the expanded upper portion of the ureter

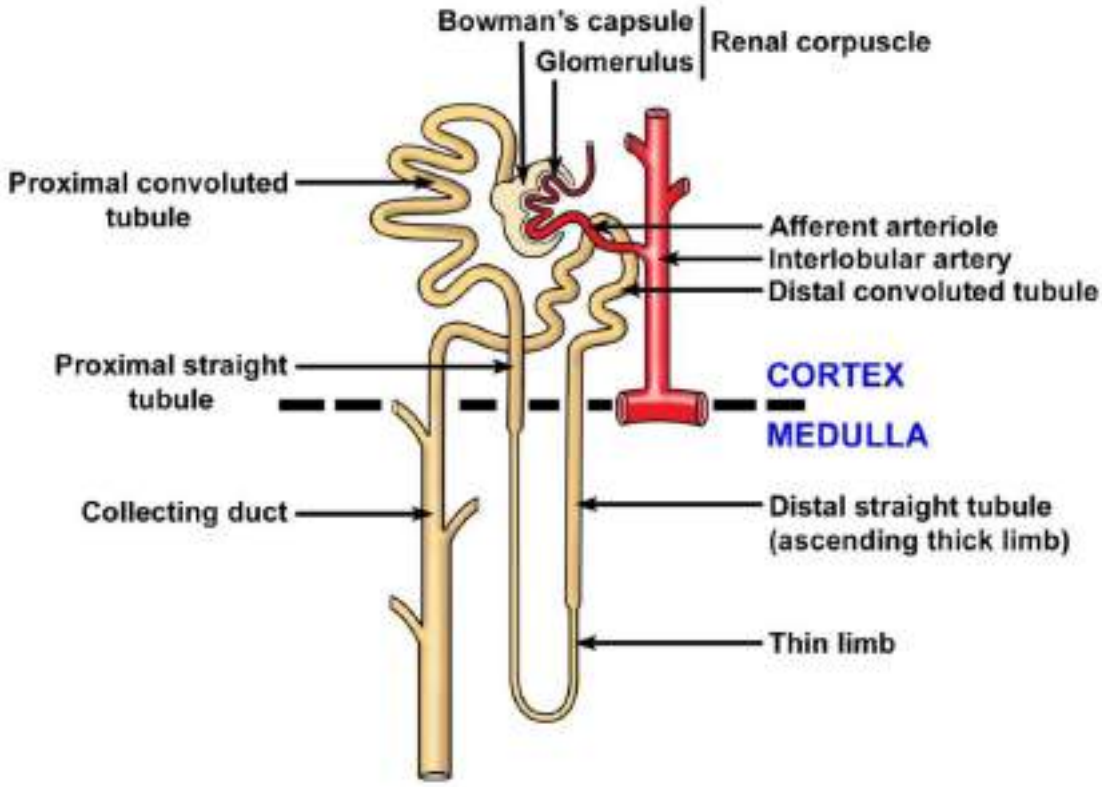

FIGURE 15.2. The nephron, collecting tubule, and associated blood supply.

THE NEPHRON

I. 1.5-2 million per kidney

II. **Renal corpuscle *(images)***

A. Located in the cortical labyrinth

B. Components

1. **Glomerulus**. A tuft of fenestrated capillaries, whose pores lack diaphragms; filter blood. Formed by an afferent arteriole, the glomerulus indents into Bowman's capsule like a baseball fits into a baseball glove. Blood leaves the glomerulus via the efferent arteriole.

2. **Bowman's capsule**. Double-walled, epithelial capsule with central space called **Bowman's space**; surrounds the glomerulus and receives the fluid filtered from the blood

a. **Parietal layer**. Outer layer, simple squamous epithelium which is reflected at the vascular pole of the renal corpuscle to become the visceral layer; continuous with the proximal tubule at the urinary pole

b. **Visceral layer**. Inner layer surrounding the glomerulus. Consists of a single layer of modified epithelial cells called **podocytes**. The radiating foot processes of these cells give rise to many secondary processes called **pedicels**. Pedicels of adjacent podocytes interdigitate and surround the glomerular capillaries. The slits *(***filtration slits***)* between the pedicels are bridged by **slit diaphragms**.

3. **Filtration barrier**. Barrier between blood in glomerular capillary and space of Bowman's capsule

   a. Fenestrated endothelium of glomerular capillary

   b. Thick, fused basal laminae of the podocytes and the glomerular endothelial cells

   c. Slit diaphragms between pedicels of visceral layer of epithelium

4. Poles of the glomerulus

   a. **Vascular pole**. Where afferent and efferent arterioles enter and leave the renal corpuscle, respectively

   b. **Urinary pole**. Where the parietal layer of Bowman's capsule is continuous with the proximal convoluted tubule

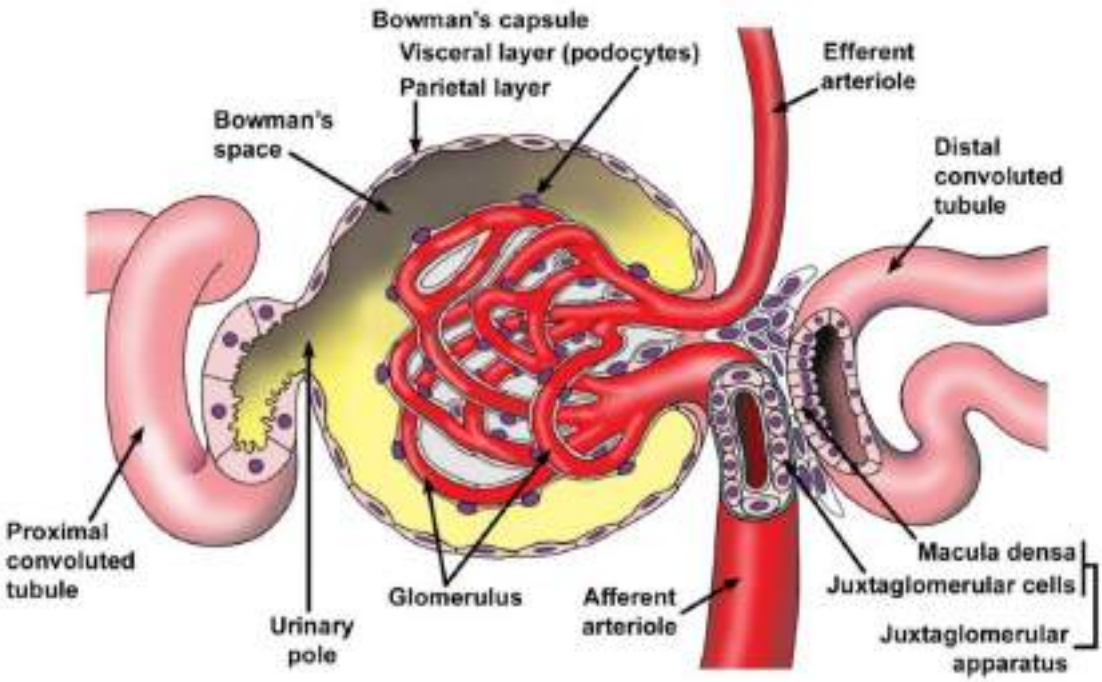

FIGURE 15.3. The renal corpuscle and associated structures.

III. Renal tubule ***(images)***

A. The glomerular filtrate of the blood continues from Bowman's space into the renal tubule, which meanders first through the cortex, then the medulla, then back to the cortex, and finally enters the collecting duct.

B. Regions of the renal tubule

1. Listed in order are regions of the renal tubule through which urine passes

    a. **Proximal convoluted tubule**

    b. **Proximal straight tubule**

    c. **Thin limbs**

    d. **Ascending thick tubule (distal straight tubule)**

    e. **Distal convoluted tubule**

2. **Proximal tubule, convoluted portion**

    a. Located in labyrinth of cortex; highly convoluted

    b. Interconnects parietal epithelium of Bowman's capsule with straight portion of proximal tubule

    c. Composed of a simple cuboidal epithelium with microvilli; cells possess numerous infoldings of the basal plasma membrane and many mitochondria

    d. Absorption of glucose, amino acids, and the majority of salt and water occur here.

3. **Loop of Henle**. Located in medullary tissue (i.e., medullary ray and medulla)

    a. **Proximal tubule, straight portion (thick descending limb of the loop of Henle)**

        i. Located in the medullary ray (in cortex) and continues into the medulla

        ii. Interconnects proximal convoluted tubule with thin limb of Henle's loop

        iii. Histology is identical to that of the proximal convoluted tubule

iv. Absorption of same substances as in proximal convoluted tubule

b. **Thin segment**

i. Found in medulla

ii. Interconnects proximal straight tubule with distal straight tubule

iii. Frequently makes the "loop" in the loop of Henle

iv. Composed of a simple squamous epithelium

v. Actively pumps out chloride, with sodium following passively, to produce a hypertonic urine

c. **Distal tubule, thick ascending limb of the loop of Henle.**

i. Begins in the medulla and continues into the medullary ray (in cortex)

ii. Interconnects thin segment with distal convoluted tubule

iii. Composed of a simple cuboidal epithelium with inconsistent microvilli. The cytoplasm is less acidophilic and the lumen is wider than in the proximal tubule. The basal plasma membrane is extensively infolded with numerous mitochondria between the folds.

iv. Returns to a glomerulus to form part of the juxtaglomerular apparatus.

v. Major site of salt and water control in the body

4. **Distal tubule, convoluted portion**

a. Located in the labyrinth portion of cortex; highly convoluted

b. Interconnects the ascending thick limb with collecting tubule

c. Histology is identical with the distal straight tubule

d. Major site of salt and water control in the body

C. **Juxtaglomerular (JG) apparatus**

1. Located at the vascular pole of a nephron; helps regulate blood pressure

2. Composition

    a. **Juxtaglomerular cells**. Modified smooth muscle cells in wall of an afferent arteriole

    b. **Macula densa**. Cluster of modified cells in the wall of a the ascending thick limb adjacent to the juxtaglomerular cells. The clustering of cells, and therefore of their nuclei, gives the appearance of a "dense spot" in the wall of the distal convoluted tubule.

3. Monitors the tonicity of the urine in the tubule. The macula densa affects the adjacent JG cells to adjust their production of renin, an enzyme that aids in regulating blood pressure.

EXCRETORY TUBULES AND DUCTS AND EXTRARENAL PASSAGES *(images)*

I. Separate embryological origin from the nephron

II. Components

A. **Collecting tubule**

1. Composed of simple cuboidal to simple columnar cells; usually displays distinct lateral boundaries between cells

2. Drains urine from the distal convoluted tubule of many nephrons in the cortical labyrinth, enters the medullary ray in the cortex and descends into the medulla

3. Joins with other collecting tubules to form the papillary ducts (of Bellini)

4. Aids in concentrating the urine

B. **Papillary ducts (of Bellini)**. Located deep in the medullary pyramid near the minor calyces; composed of a tall, pale, simple columnar epithelium. Empty into the minor calyx at the area cribosa at the apex of each pyramid

C. **Minor** and **major calyces**. Transport urine to the renal pelvis and into the ureter; lined by **transitional epithelium**

D. **Renal pelvis**. Expanded origin of the ureter, lined by transitional epithelium; formed by the union of major calyces

E. **Ureter**. Muscular tube connecting the renal pelvis and the urinary bladder, lined by transitional epithelium; two layers of smooth muscle in the upper two-thirds, inner longitudinal and outer circular, with the addition of a third outer longitudinal layer in the lower one-third

F. **Urinary bladder**. Lined by a transitional epithelium, a stratified cuboidal epithelium specialized to provide for distension of the organ; a thick muscular wall contains three interlacing layers of smooth muscle.

BLOOD SUPPLY OF THE KIDNEY

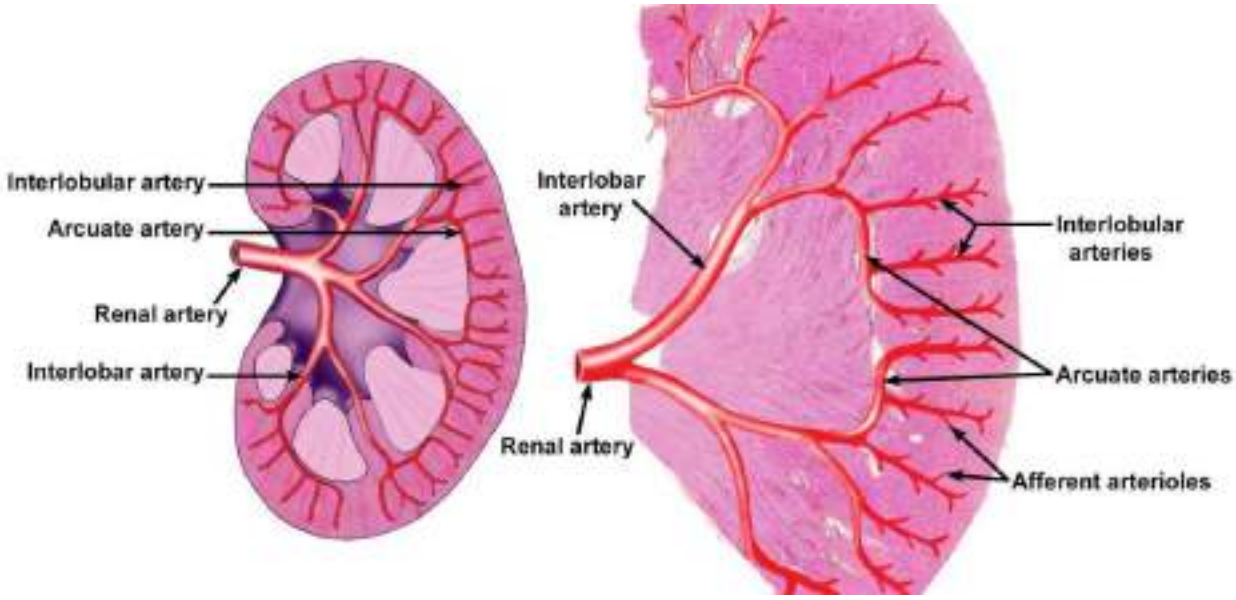

FIGURE 15.4. Blood supply of the kidney

I. **Renal artery**. A branch of the aorta, enters the kidney at the *hilus;* branches to form the interlobular arteries

II. **Interlobar arteries**. Lie between adjacent pyramids in renal columns and branch into arcuate arteries

III. **Arcuate arteries**. Arch between medulla and cortex; give rise to interlobular arteries

IV. **Interlobular arteries**. Branch perpendicular to the arcuate artery in the cortex and lie between adjacent lobules; supply a number of afferent arterioles

V. **Afferent arterioles** supply the glomerulus, entering at the vascular pole of the renal corpuscle

VI. **Glomerulus**. A tuft of capillaries protruding into Bowman's capsule where blood is filtered.

VII. **Efferent arteriole** exits from the glomerulus and forms either **peritubular capillaries**, which nourish the convoluted tubules, or the **vasa recta**. The vasa

recta parallel the straight portions of the renal tubule into the medulla and play an important role is concentrating the urine.

Dental Indices

Dr. Azhar Alkamal

Epidemiological methods of the study require the conditions be measured and quantified accurately based on sound scientific principles. One of the major problem in studying dental diseases and its factors is the development of a suitable, practicable method for recording the occurrence and severity of disease. Quantitative measurement of disease most commonly relies on "index". So, dental index is the main tool of epidemiological studies in dental diseases to measure incidence, prevalence and severity.

Index

A numerical value describing the relative status of a population on a graduated scale with definite upper and lower limits, which is designed to permit and facilitate comparison with other populations classified by the same criteria and methods.

Objectives

1. To increase understanding of the disease process, leading to methods of control and prevention.
2. To discover populations at high and low risk.
3. To define the specific problem under investigation.

Ideal properties of an index

1- **Clarity, simplicity, and objectivity**:

- The examiner should be able to carry the rules of the index in his mind.

- The index should be easily to apply, so there is no undue time lost during examination.

- The index criteria should be clear and unambiguous.

2- **Validity:**

The index should be measure what it is intended to measure, so it should be correspond with clinical stages of the disease, ex: numbers of missing teeth in adults are not a valid measure of caries activity.

3- **Reliability:**

The index should measure consistently at different times and under a variety of conditions. Reproducibility: the ability of the same or different person to use the index in the same way.

4- **Quanti fiability:**

The index should be a mean able to statistical analysis. The status of a group can be expressed by a number that corresponds to a relative position on a scale from zero to the upper limit.

5- **Sensitivity:**

The index should be able to detect reasonably small shift, in either direction in the group condition.

6- **Acceptability:**

The use of the index should not be painful or demeaning to the subject.

Uses of dental indices

1- To study oral health status of individuals and population.
2- To study prevalence and incidence of diseases.
3- To provide data for epidemiological studies.
4- For planning of oral health policy.
5- To evaluate the effectiveness of oral health programs.
6- To provide data for research to find out etiological and predisposing factors for the diseases.
7- To evaluate the success of various preventive programs.
8- To compare oral health status of individuals and population.

Classification of indices

Based upon the:

A-**Direction in which their scores can fluctuate**:

1- Irreversible index ex: DMF

Index that measures conditions will not return to the normal state. Once establish cannot decrease in value on subsequent examinations.

2- Reversible index ex: GI

Index that measure conditions that can be return to the normal state. Reversible index scores can decrease or increase in value on subsequent examinations.

3- Composite index ex: Russell's PI

Index that measure conditions which can be return to the normal state and conditions that will not retain to the normal state.

B- **The extent to which areas of oral cavity are measured:**

1- Full mouth index ex: Russell's PI

These indices measure the patient's entire periodontium or dentition.

2- Simplified index ex: OHI-S

These indices measure only a representative sample of the dental apparatus.

C- **The entity which they measure:**

1- Disease index **D** MF
2- Treatment index DM **F**
3- Symptom index PBI

D- **The special categories**:

1- Simple index PlI
Index that measure the presence or absence of condition.

2- Cumulative index DMF
Index that measure all the evidence of a condition, past and present.

Scale

1- **Ordinal scale**: it is a scale of measurement that list conditions in some order of severity without attending to define mathematical relation between the categories.

GI	0	1	2	3
	no inflammation	mild	moderate	severe

2- **Nominal scale**: a scale that gives name to different condition.
OHI good poor fair

3- **Interval or ratio**: a scale that uses number in measuring and has mathematical relation to each other.
In ratio scale there is a true zero, GI 0=no inflammation.
In interval scale there is no true zero.

A numerical value describing the relative status of a population on a graduated scale with definite upper and lower limits, which is designed to permit and facilitate comparison with other populations classified by the same criteria and methods.

I-Indices used for dental caries assessment

1-For coronal caries A- Permanent teeth

B -primary teeth

2-For root caries

1- Coronal caries

A - Permanent teeth index:

Decayed – Missing - Filled index (DMF) which was introduced by Henry et al in 1938 and modified by WHO

1- DMF teeth index (DMFT) -which measure the prevalence of dental caries
2- DMF teeth index (DMFS) – which measure the severity of dental caries

D component:

Used to describe (Decayed teeth) which include: -

1- Carious tooth
2- Filled tooth with recurrent decay.
3- Only the roots are left.
4- Defect filling.
5- Temporary filling.
6- Filled tooth surface with other surface decayed.

M component:

Used to describe (Missing teeth due to caries)

1- Tooth that extracted for reasons other than caries should be exclude, which include:
   a- Orthodontic treatment.
   b- Impaction.
   c- Periodontal disease.
2- Un erupted teeth.
3- Congenitally missing.
4- Avulsion teeth due to trauma or accident.

F component

It is used to describe filled teeth due to caries.

Teeth stored for reason other than dental caries should be excluded, which are:

a- Trauma (fracture).
b- Hypoplasia (cosmetic purposes).
c- Bridge abutment (retention).
d- Seal a root canal due to trauma.
e- Fissure sealant.
f- Preventive filling.

Note:

A tooth considered to be erupted when just the cusp tip of the occlusal surface or incisor edge is exposed. The excluded teeth in the DMF index are: 1- Supernumerary teeth.

2- Third molar (Henry et al) only.

Principle and rules in recording

1- **DMFT:**
   a- A tooth may have several restorations but it counted as one tooth filling, F.
   b- A tooth may have restoration on one surface and caries on the other; it should be counted as decay, D.
   c- No tooth must be counted more than once, D M F or sound.
2- **DMFS**
   Each tooth was recorded scored as 5 surfaces for posterior teeth and 4 surface for anterior teeth.

Calculation of DMFT\ DMFS:

1- For individual DMF = D+M+F
2- For population mean DMF = Total DMF / Total no. of the subjects' exam.

Maximum score 1- DMFT=32

2- DMFS= 12*4+20*5=48+100=148

Minimum score=zero

B - Primary teeth index:

1- dmft / dmfs maximum score: dmft=20 dmfs=88
2- deft /defs which was introduced by Gruebble in 1944
d = decayed tooth

e = extracted tooth due to caries or badly carious tooth indicated for extraction.

f = filled tooth.

3- dft /dfs

In which the missing teeth are ignorant, because in children it is difficult to make sure whether the missing tooth was exfoliated or extracted due to caries or due to serial extraction.

Mixed dentition

Each child is given a separate index, one for permanent dentition and other or primary dentition.

How could you differentiate between tooth missing due to caries or due to exfoliation?

1- By age of the patient if it is near to exfoliation time or not.
2- The shape of ridge is concave in carious missing tooth and straight in exfoliated one and permanent successor may be seen.
3- DMF / dmf index is higher in association with carious missing tooth especially adjacent and the contra lateral teeth.
4- Bad oral hygiene mainly associated with carious teeth.

How could you differentiate between tooth missing due to caries or due to orthodontic treatment?

1- Crowding or appliance may be seen in orth. Treatment.
2- By type of teeth, in ortho treatment most teeth should be extracted are 4 or 5 / c or d, while in carious missing teeth any teeth may be involved.
3- Bilateral and/ or opposing missing generally associated with ortho treatment, while in carious missing teeth is not necessary

4- DMF / dmf index is higher in association with carious missing tooth especially adjacent and the contra lateral teeth with bad oral hygiene mainly associated with carious teeth.

Dental caries severity classification scales

(D1-D4 / d1-d4) which was introduced by WHO in 1979 as an aid to diagnosing coronal caries.

Score	**Criteria**
D1	Initial caries, no clinically detectable loss of substance. For pits and fissures, there may be staining, discoloration, rough spot do not catch the probe. For smooth surfaces, white, opaque areas with loss of luster may be seen.
D2	Enamel caries. Loss of tooth substance in bits, fissures or on smooth surfaces. But no softened floor or wall or undermined enamel. No evidence of cavitations has penetrated the dentin.
D3	caries of dentin, softened floor, undermined enamel or a softened wall or the tooth has temporary filling.
D4	pulp involvement, deep cavity with probable pulp involvement. Pulp should not be probed.

2-Root caries index (RCI):

This index was introduced by Ralph in 1979. RCI index is based on the requirement that gingival recession must occur before root surface lesions begin. Therefore, only teeth with gingival recession are examined.

The calculation of RCI: $$RCI = \frac{(R\text{-}D) + (R\text{-}F)}{(R\text{-}D) + (R - F) + (R\text{-}N)} * 100$$

(R-D) is no. of root surfaces with decay. (R-F) is no. of root surface with permanent filling. (R-N) is the no. of sound root surfaces.

II -Indices used for oral hygiene assessment

Simplified oral hygiene index (OHI-S)

OHI-S was introduces by Greene and Vermillion in 1964 which is composed of two components

1- **Simplified debris index.**
2- **Simplified calculus index**.

-Only 6 teeth, one surface for each tooth (lingual surface for the lower 6 and the buccal for others) should be examined.

-Partial erupted, crowned and fractured teeth should be excluded.

-There is a substitution for excluded teeth.

-This index measures the extension of debris and calculus.

Debris index

Score	Criteria
0	No debris.
1	Soft debris covering not more than 1/3 of the tooth surface.
2	Soft debris covering more than 1/3, but not more than 2\3 of the tooth surface.
3	Soft debris covering more than 2/3 of tooth surface.

Calculus index

Score	Criteria
0	No calculus.
1	Super gingival calculus covering not more than 1/3 of tooth surface.
2	Supra gingival calculus covering more than 1/3 but not more than 2/3 of tooth surface, or the present of flecks of sub gingival calculus or both.
3	Supra gingival calculus covering more than 2/3 of the tooth surface, or continuous heavy band of sub

gingival calculus around the cervical portion of the tooth or both.

Calculation

DI = Total scores / no. of teeth exam 0 ⟶ 3

CI = Total scores / no. of teeth exam. 0 ⟹ 3

OHI-S = DI + CI 0 ⟹ 6

C- Index used for plaque and debris assessment

Plaque index (PlI) which was introduced by Silness and Löe in 1964

-Used together with GI, and should be preceded the gingival examination.

-Wisdom teeth are excluded.

-Used all teeth (28) or selected (6).

-No substitution for any missing tooth.

-Used on all surfaces or selected surfaces.

-The six index teeth are:

Score	Criteria
0	No plaque
1	A film of plaque adhering to the free gingival margin and adjacent area of the tooth, which cannot be seen with the naked eye. But only by using disclosing solution or by using probe.
2	Moderate accumulation of deposits within the gingival pocket, on the gingival margin and/ or adjacent tooth surface, which can be seen with the naked eye.
3	Abundance of soft matter within the gingival pocket and / or on the tooth and gingival margin.

This index measures the thickness of the plaque on the gingival one third.

Calculation:

1-individual: PLI = Total scores / number of surfaces exam

2-population PIL = Total scores /_ number of subjects exam.

D – Indices used for calculus assessment:

Calculus surface index (CSI) was introduced by Ennever et al in 1961. CSI assesses the present or absence of supra and / or sub gingival calculus by visual or tactile examination, regardless the quantity of calculus.

Criteria Absence = 0

Present = 1

* 4 or 6 mandibular anterior teeth are examined.

* Each tooth divided into 4 areas.

Calculation:

CSI = Total number of scores 0-----16 or 0-----24

E- Index used for dental stain

Stain is a discoloration accumulating on the surfaces of teeth, restoration, calculus, and prosthesis. Stain could be extrinsic or intrinsic.

1- **Extrinsic stain: -**

The discoloration is outside the tooth substance and lies on the tooth surfaces or in the acquired pellicle. It is caused by

a- food like coffee or tea
b- smoking
c- medication and mouth rinses

Stain may be containing calcium, carbon, iron, nitrogen, sulfur, oxygen, and copper. Stain may increase roughness of teeth surface aiding in plaque accumulations and increase the risk of periodontal disease. Extrinsic stain can be removed by brushing or professional polishing.

2- Intrinsic stain: -

It occurs due to the change in the structural composition or thickness of the dental hard tissue. Metallic diseases and systemic factors may be affecting the developing dentition and cause discoloration.

Index that used to measure the extrinsic stain was stain index of löe and Silnees 1963. The six surfaces examined for the OHI-S are selected from posterior and two anterior teeth.

Criteria for classifying stain

0	no stain
1	light stain (yellow to light brown)
2	moderate stain (brown)
3	heavy stain (dark brown to black)

Stain index = totaling of scoring / number of tooth surface exam.

F- Indices used for gingival disease assessment:

Gingival Index (GI) was introducing by Löe and Silness in 1963.

GI could be used in all teeth or selected teeth and in all surfaces or selected surfaces.

The examination should be done by blunt probe. Partially erupted teeth, retained roots, teeth with per apical lesion and third molars should be excluded and there is no substitution.

Score	**Criteria**
0	No inflammation.
1	Mild inflammation, slight change in color, slight edema, no bleeding on probing.

2	Moderate inflammation, moderate glazing, redness, edema and hypertrophy, bleeding on probing.
3	Sever inflammation, marked redness and hypertrophy, ulceration, tendency to spontaneous bleeding.

0------1 Mild gingivitis

1.1-----2 Moderate gingivitis

2.1-----3 Sever gingivitis

Calculation:

1- individual **GI =** Total scores / No of surfaces exam.

2-population **GI** = Total scores / No of subjects' exam.

Papillary – Marginal – Attachment index (PMAI)

-Was introduced by Maury and Schour in 1944.

-it measures the affected gingival rather than severity.

-the facial surface of the gingival was divided into three parts.

1-papillary gingival.

2-marginal gingival.

3-attached gingival.

Only these teeth should be scored 54321 12345

54321 12345

Score	Papillary g.	Marginal g.	Attached g.
0	Normal	normal	normal
1	slight increase in size	slight increase in size	slight increase in size +loss of stippling
2	increase in size +bleeding	increase in size + bleeding	increase in redness +pocket formation
3	excessive increase in size +spontaneous bleeding	excessive increase in size +spontaneous bleeding	advanced p.dentitis + deep pocket
4	necrosis	necrosis	----------
5	atrophy of papilla	gingival recession	----------

Calculation:

$$\text{PG. or MG. or AG.} = \frac{\text{total score}}{\text{No. of areas exa.}}$$

P M A I = P + M + A

Papillary Bleeding Index (PBI)

Was introduced by Muhlemann in 1977 which is based on bleeding following gentle probing of interdental papilla by periodontal probe.

Score	Criteria
0	no bleeding
1	a single bleeding.
2	Several isolated bleeding points.
3	The interdental triangle fills with blood shortly after probing.
4	Profuse bleeding after probing.

F- Indices used for periodontal disease assessment:

Periodontal Disease Index (PDI) was introduced by Ramfjord in 1959.

PDI index composed of three component, which used Ramfjord teeth.

1- **Gingival and periodontal component.**

a-The criteria ranged from 0 = normal

1, 2, 3, = gingivitis

4, 5, 6, = periodontitis

b- All areas (M, D, B, L,) are score as a one unit.

Calculation Total score / no of teeth exam

2- **Plaque component:**

a- The criteria ranged from 0---3

b- All areas (B, L, M, D,) are scored as one unit

Calculation = total score / number of teeth exam

3-**calculus component:**

b- The criteria ranged from 0-----3

c- Only facial and lingual surface are evaluate, and scored separately.

Calculation total scores / number of surfaces exam.

G – Indices used for dental fluorosis assessment:

Dental fluorosis: It is a hypoplasia or hypomineralization of tooth enamel produce by the chronic ingestion of excessive amount of fluoride during the period of tooth development.

Dean's Fluorosis Index – Modified criteria…was introduced by Dean in 1942.

Classification	Criteria
Normal	No dental fluorosis
Questionable	The enamel discloses slight aberrations from the translucency of normal enamel ranging from a few white flecks to occasional white spots.
Very mild	Small, opaque, white areas scattered irregularly over the tooth, but not involving 25% of the tooth surfaces.
Mild	The white opaque areas in the enamel of teeth are more extension. But not involve as much as 50% of tooth.
Moderate	All enamel surfaces of teeth are affected and surfaces subject to attrition show wear, brown stain is a disfiguring feature.
Sever	all enamel surfaces of teeth are affected and hypoplasia Is so marked that the general form of the tooth may be affected, pitting surface with brown stain.

Note:

1-each tooth present in the mouth was examined.

2-the severity of dental fluorosisin a group of population, fluorosis index was used (CFI).

Fluorosis category	Numerical weight
Normal	0
Questionable	0.5
Very mild	1
Mild	2

Moderate 3

Sever 4

CFI = Sum of numerical weight / no.of individual exam.

Simplified Fluoride Mottiling Index (FMI)

Was introduce by Rahmatulla and Rajasekhar in 1984.

Only facial surfaces of the six upper and lower anterior teeth are examined which are esthetically important.

Scores	**Criteria**
0	No involvement of facial surface.
1	Less than 1/3 of the facial surface shows evidence of lesion.
2	A bout 1/3 but less than 2/3 of the surface affected.
3	Over 2/3 of facial surface involved.
4	Brownish black discoloration of entire facial surface.

Note

Ramfjord teeth are: Permanent deciduous

6		1 4	E		A D
1 4		6	D A		E

Community dentistry

Dr. Hind Thyab

Basic epidemiology and Measures of Central Tendency

Scope of Epidemiology

- 1. Causation of the disease.
- 2. Natural history of the disease.
- 3. Health status of the population.
- 4. Evaluation of Interventions.

Applications of epidemiology in public health

1. Preventing disease and promoting health.
2. Community health assessment (Community Diagnosis) and priority setting.
3. Improving diagnosis, treatment and prognosis of clinical diseases.
4. Evaluating health interventions and programmers.

Measuring Disease Frequency

Incidence and Prevalence :

- These are fundamentally different ways of measuring disease frequency.
- The incidence of disease represents the rate of occurrence of new cases arising in a given period in a specified population, while
- prevalence is the number of existing cases (old+ new) in a defined population at a given point in time.

Incidence : "Number of new cases occurring in defined population during specified period of time"

- Incidence = Number of new cases during given period / Population at risk x 1000

Prevalence : Prevalence is total no of existing cases (old + new) in a defined population at a particular point in time or specified period.

- Prevalence = Total no of cases at given point of time / Estimated population at time x 100

- Example : In **2019**, the number of patients at the practice (**total population**) was **39,640**. The number of people at that time with COVID-19 was 1780. Therefore, the **prevalence** equals (**1780/39640**) × 100 = 4.5% .
- In **2020**, the number of patients at the practice had increased to **40,000**. The number of cases of COVID in 2020 had risen to 1826. The **prevalence in 2020** therefore was **(1826/40000)** × 100 = **0.0456** giving us 4.6% of the population.
- We can see the prevalence of COVID-19 in this population only changed by approximately 0.1%.
- The number of new cases in 2020 compared to 2019 is 1826-1780, making the difference 46. Therefore, the **number of new cases** at the practice is **46 per year**, which makes the **incidence 46/40,000 =0.00115 (1.15 per 1000 population)**. (For simplicity this is assuming those 46 were all new patients with onset of COVID in 2020).

Tools Of Measurements

Basic tools are :

1. Rate
2. Ratio
3. Proportion • Used for expression of disease magnitude.

- **Rate :** A "Rate" measures the occurrence of some specific event in a population during given time period.
- A rate is a ratio of the form a/ (a+b)
- a = the frequency of events during a certain time period
- a+b = the number at risk of the event during that time period
- Example : 8 death per 100,000 person at one year .

* **Properties of Rates :**

* The calendar time period is the same in both the numerator and denominator of a rate .

* A rate expresses the relative frequency of an event per unit time ("risk").

* **Examples of Rates :**
* Calculate the rate of death for children under 4 years due to malignancy at 2020 , (total death for children under 4 years at 2020 due to malignancy are 4 , total death for children under 4 years at 2020 are 72)
* Rate = „ total # deaths ages 1–4 due to malignancy in calendar year / total # deaths aged1 −4 in calendar year x 100
* Rate = (4 / 72) 100 = 5.5

- **Ratio :** Ratio measures the relationship of size of two random quantities.

• Ratio = x / y
• Example : Sex – Ratio , Doctor Population Ratio.

* Method for calculating a ratio

$$\text{Ratio} = \frac{\text{Number or rate of events, items, persons, etc. in one group}}{\text{Number or rate of events, items, persons, etc. in another group}} \times 10^n$$

* Note : that in certain ratios, the numerator and denominator are different categories of the same variable, such as males and females, or persons 20–29 years and 30–39 years of age. In other ratios, the numerator and denominator are completely different variables, such as the number of hospitals in a city and the size of the population living in that city.
* 10^n : To get a more easily understood result, you could set 10^n
* 10^n (constatnt) may be 100 , 1000 , or 10.000

* **Example :** A city of 4,000,000 persons has 500 clinics. Calculate the ratio of clinics per person.
* $500 / 4{,}000{,}000 \times 10^n = 0.000125$ clinics per person
* To get a more easily understood result, you could set $10^n = 10{,}000$. Then the ratio becomes:
* $0.000125 \times 10{,}000 = 1.25$ clinics per 10,000 persons

- **Proportion :** Proportion is ratio which indicates the relation in a magnitude of a part of whole.
- The numerator is always part of denominator .
- Usually expressed in percentage .

* **Method for calculating a proportion**

* Proportion = $\frac{\text{Number of persons or events with a particular characteristic}}{\text{Total number of persons or events, of which the numerator is a subset}} \times 1o^{n}$

* For a proportion, 10^n is usually 100 and is often expressed as a percentage.
* **Example :** Calculate the proportion of men in the dental clinic follow-up who were diabetics. (total no. of men = 3,151 , diabetic = 189)
* Numerator = 189 diabetic men

  Denominator = Total number of men = 189 + 3,151 = 3,340
* Proportion = (189/3,340) × 100 = 5.66%

Measurements in Epidemiology

1. Measurement of mortality.
2. Measurement of morbidity.
3. Measurement of disability.
4. Measurement of natality.
5. Measurement of presence or absence of attributes.
6. Measurement of health care need.
7. Measurement of environmental & other risk factors.
8. Measurement of demographic variables.

Measures of Central Tendency

♣ Measures of central tendency are statistical measures which describe the position of a distribution.

♣ They are also called statistics of location, and are the complement of statistics of dispersion, which provide information concerning the variance or distribution of observations.

♣ In the univariate context, the mean, median and mode are the most commonly used measures of central tendency.

1. **mean** : is a mathematical average and it is the most popular measures of central tendency. It is frequently referred to as 'mean' it is obtained by dividing sum of the values of all observations in a series (ΣX) by the number of items (N) constituting the series.

2. **Median** : is a central value of the distribution, or the value which divides the distribution in equal parts, each part containing equal number of items. Thus it is the central value of the variable, when the values are arranged in order of magnitude.

Connor has defined as " The median is that value of the variable which divides the group into two equal parts, one part comprising of all values greater, and the other, all values less than median"

- **Calculation of Median –Discrete series :**

i. Arrange the data in ascending or descending order.

ii. And select the median data

If there are two median item or value (data) , so sum the two data and divided ye two .

Example : 1 , 5 , 6 , 9 , 8 , 8 ,9, 4

1. asending order : 1 , 4 , 5 , 6 , 8 , 8, 9 , 9

2. median = (6 + 8) / 2 = 7

3. **Mode** : is the most frequent value or score in the distribution. It is defined as that value of the item in a series. It is denoted by the capital letter Z. highest point of the frequencies distribution curve.

- Example : the data : 10 , 20 , 40 , 10 , 70 .

- The **mean** is found by adding all of the numbers together and dividing by the number of items in the set: 10 + 10 + 20 + 40 + 70 / 5 = 30.
- The **median** is found by ordering the set from lowest to highest and finding the exact middle. (10 , 10 , 20 , 40 , 70), The median is just the middle number: 20.
- The **mode** is the number that appears the most often. In this case the mode is : 10 .

Conclusion :

• A measure of central tendency is a measure that tells us where the middle of a bunch of data lies. • Mean is the most common measure of central tendency. It is simply the sum of the numbers divided by the number of numbers in a set of data. This is also known as average.

• Median is the number present in the middle when the numbers in a set of data are arranged in ascending or descending order. If the number of numbers in a data set is even, then the median is the mean of the two middle numbers. • Mode is the value that occurs most frequently in a set of data

Measure of Dispersion :

- Dispersion is the scatteredness of the data series around it average. Dispersion is the extent to which values in a distribution differ from the average of the distribution.

- **Why we need measures of dispersion? (Significance)**

- Determine the reliability of an average ,
- Serve as a basis for the control of the variability
- To compare the variability of two or more series and
- Facilitate the use of other statistical measures.

1. Range : the range is the simplest measure of variation to find. It is simply the highest value minus the lowest value.

RANGE = MAXIMUM – MINIMUM.

Since the range only uses the largest and smallest values, it is greatly affected by extreme values, that is - it is not resistant to change.

2. **Variance :** the range only involves the smallest and largest numbers, it would be desirable to have a statistic which involved all the data values. The first attempt one might make at this is something they might call the average deviation from the mean. The problem is that this summation is always zero. So, the average deviation will always be zero. That is why the average deviation is never used. So, to keep it from being zero, the deviation from the mean is squared and called the "squared deviation from the mean". This "average squared deviation from the mean" is called the variance.
3. **Standard Deviation :** To overcome the problem of squaring in variance to get the units back to the same as the original data values, the square root is taken. For small samples the sum of the squares is divided by the number of observations minus one instead of the number of observations. This is because "degrees of freedom" must be used.

4. **The coefficient of variation (CV) :** is defined as the ratio of the standard deviation to the mean It shows the extent of variability in relation to the mean of the population.

   Coefficient of variation = standard deviation / mean

The extra and intra oral examination

dr. Hind thyab

Extra oral examination

The extra oral examination should be conducted routinely, and most practitioners conduct it with each new assessment. This helps to reduce the likelihood of missing any areas of concern.

1. Face

The face should be assessed, and any abnormal findings noted in the clinical records. These include swelling, discolouration and any asymmetry. Asymmetry can occur due to swellings originating from both dental and non-dental causes such as infection, neoplastic growths and hypertrophy.

2. Head

a. Similar to the examination of the face, the head should also be assessed for any swellings, discolouration or asymmetry. Where a patient's scalp is visible, this should be assessed visually as this can be a common site for basal cell carcinomas and the patient may not be aware of them.

b. The assessment of the patient's head should include the palpation of the major lymph nodes. Findings such as enlargement, fixation and tenderness of lymph nodes should be noted. This is particularly important as non-tender and fixed lymph nodes can be indicative of malignancies whereas tender lymph nodes can sometimes occur in conjunction to infections, both of dental and non-dental origin.

c. The temporomandibular joint (TMJ) is also assessed. This should be assessed both at rest and when the patient is carrying out mandibular movements. The patient can be asked to complete movements such as opening and closing their jaw, moving it side to side as well as thrusting the mandible forward in order to assess the TMJ. Any pain, clicking, limitation of movement or opening, grating or tenderness as well as any deviation or deflections should be noted.

3. Neck

a. Similar to the assessment of the patient's head, the neck should also be palpated to assess the major lymph nodes. Again, any enlargement, fixation or tenderness of the lymph nodes should be noted.

b. Any lumps, swelling, tenderness or abnormalities should also be noted.

The intra oral soft examination

The intra oral examination is divided into soft tissue and hard tissue examination. Similarly to the extra oral examination, the intra oral examination should be completed with every new assessment and should be conducted in a systematic manner in order to minimize the chances of an area not being assessed.

The areas assessed include:

1. Lips

Lips are normally smooth with a homogenous pink appearance and the vermillion border is even and distinct. Symmetry, tissue consistency, texture, colour, as well as any lumps should be noted. Ensure to assess the commissures as this is a common site for pathological conditions such as Candida albicans, angular cheilitis as well as nutritional deficiencies.

2. Buccal and labial mucosa

a. The buccal and labial mucosa should be moist and red in appearance. On palpation it should be soft with no indurations or palpable lesions or lumps. Stensen's or the parotid duct can also be identified on the buccal mucosa adjacent to the upper molars. Linea alba and Fordyce spots or granules are common findings on the buccal mucosa and should be noted, but do not require treatment. Linea alba can sometimes occur due to stress and as a result of bruxism. It is a hyper-keratinised area in line with the occlusal plane.

b. Findings such as cheek biting, burns and ulcers may be seen and should be noted and reviewed at appropriate intervals, most commonly in two weeks.[3] Changes such as erythroplakia (red patch) and speckled leukoplakia (red and white patch) can be indicative of neoplastic changes and therefore should be noted in the clinical record and referred appropriately.

3. Floor of mouth

a. The patient should be asked to raise their tongue to allow the clinician to visualise the floor of mouth directly. Using the back of a mirror may be useful to help see the most posterior aspects of the floor of mouth. In most patients the tissues should be moist in appearance and can be vascular. Normal findings include the sublingual caruncle and folds, and the lingual frenum.

b. Abnormal findings include swelling, ulceration, mucoceles, sialoliths and neoplastic changes similar to those mentioned above *amongst* other findings.

4. Tongue

a. The examination is particularly important when screening for oral cancer as a common site for oral cancer to occur is the lateral border of the tongue.

b. To examine the dorsum of the tongue, ask the patient to stick their tongue straight out. Then get the patient to move their tongue to the left and the right to examine the lateral border of the tongue. Using a mirror can sometimes be useful when trying to examine the most posterior aspect of the lateral border of the tongue. The ventral aspect of the tongue can be observed by asking the patient to curl their tongue up to the roof of their mouth.

c. The tongue should be pink in appearance and symmetrical in both shape and function. There should be no palpable indurations or lumps. Common findings include fissuring of the tongue as well as papillae including filiform, fungiform and circumvallate papillae.

d. Any abnormal findings such as geographic tongue, ulceration, leukoplakia and erythrolakia should be noted in the clinical record and reviewed and referred appropriately in accordance to local guidance.

5. Palate

a. The palate should be examined visually with the aid of illumination. The palate should be a pale pink colour and homogenous in appearance. Normal structures that may be identified are the incisive papilla, raphe, rugae, the maxillary tuberosities and the vibrating line.

b. The most common atypical findings on the palate are palatal tori and ulceration.

Findings that could be concerning and their management

it is important for dental professionals to look out for any signs or symptoms that may be concerning. Signs and symptoms commonly include:

- Persistent non-healing ulcers (present for longer than three weeks with no obvious explanation for its presence)
- A mass or lump on the lip or within the oral cavity
- Abnormal bleeding
- A red (erythroplakia) or mixed red and white (erythroleukoplakia) area
- An unexplained persistent sore throat
- Regional lymphadenopathy or unexplained neck lump
- Unexplained pain on one side of the face or neck lasting longer than four weeks
- Hoarseness that is persistent and unexplained.
- If a patient presents with any of the above signs or symptoms, then a referral on the suspected cancer referral pathway is advised. These patients are then typically seen within two weeks of the referral.

Oral health survey

Survey definition : is an investigation in which information is systematically collected but in which experimental method is not used.

Types of survey :
Cross-sectional and longitudinal Types : Descriptive and analytical

Uses of survey :
1. Providing visibility for dental issues
2. Monitoring trends in oral health and disease
3. Policy development
4. Program evaluation
5. Assessment of dental needs

Steps of survey

1. Establishing the objectives
2. Designing the investigation
3. Selecting the sample
4. Conducting the examination
5. Analyzing the data
6. Drawing conclusion
7. Publishing results

1. Establishing the objectives
• Clear
• Null hypothesis
• Describing the situation and what is to be measured

2. Designing the investigation
• Survey protocol
• Budgeting
• Emergency care and referral

Methods of data collection
• Health interview survey (face to face survey)
• Health examination survey
• Health record survey

• Questionnaire survey: mailed questionnaire , telephone interviews , face to face interviews

3. Selecting the sample

• Convenience/selected
• Random sample
• Systematic sampling
• Stratified cluster random sampling
• Multistage sampling

4. Conducting the examination

• Obtaining approval from authorities
• Instruments and supplies
• Infection control
• Examination area
• Training and calibrating examiners
• Emergency care/reference

Training and calibration

• To ensure uniform interpretation, understanding and application by all examiners of the codes and criteria for the various diseases and condition to be observed.
• Intra examiner and inter examiner variability: ability to reproduce the same diagnosis of the same condition on another occasion.
• In is measured using kappa statistics

Calibration :

Intra examiner : one examiner (two weeks between two examination).
Inter examiner : more than one examiner .

Kappa statistics

• It is used to calculate intra and inter examiner reproducibility.
• It is an index which compares the agreement against which might be expected by chance.
• Values: +1 = perfect agreement
0 = no agreement above that expected by chance
-1 = complete disagreement

5. Analyzing the data

• Manual
• Computerized
• Presentation – tables, graphs

6. Drawing conclusion

• Interpretation of analyzed data specifically related to the investigation

7. Publishing results

- Statement and purpose of the survey
- Materials and methods
- Results
- Discussion
- Conclusions
- Summary
- Recommendations

Basic oral health surveys : Surveys to collect the basic information about oral disease status and treatment needs for planning or monitoring changes in disease levels .

Objectives :

• To provide a full picture of oral health status
• To monitor changes in oral health disease
• Age related
• Irreversible – both past and present
• Extensive documentation on different socioeconomic and environmental conditions

Path finder survey

• A practical, economic survey sampling methodology
• Includes most important sub groups
• Index age groups
• Minimum expenses Stratified cluster sampling technique

Index age groups :

- 5 years (primary teeth) ,
- 12 years (permanent teeth) ,
- 15 year (adolescents) ,
- 35-44 years (adults) ,

- 65-74 years (elders) .

Types of pathfinder survey

• Pilot – includes 1-2 index age groups, provides minimum amount data to commence planning

•National – covers all important sub groups, minimum three index ages, national wise planning

Pilot surveys

• only the most important subgroups in the population

• one or two index ages

• 12 years and one other age group.

• provides the minimum amount of data needed to commence planning

National level surveys

• incorporates sufficient examination sites to cover all important subgroups of the population

• At least three of the index age groups

• suitable for collection of data for planning purposes and monitoring of oral health programmers in all countries regardless of the level of disease, availability of resources or complexity of care.

Patient sitting and examination

• chair position is a very important aspect in the success of a dental treatment.
• the correct positioning helps the operator to have a good visibility and accessibility of the oral cavity
• proper positioning of the patient and the operator, illumination and retraction for optimal visibility are the fundamental pre- requisites to proper dental treatment
• if operator maintains proper position and posture during treatment, the operator is less likely to get strain, fatigue, be more efficient and less chances of getting musculoskeletal disorders.

- **following points should be kept in mind in relation to dental chair:**

1. it should be able to provide comfort to the patient .
2. it should be able to provide total body support .
3. headrest of chair should be attached for supporting patient's chin and reducing strain on chin muscles .
4. it should be able to provide maximum working area to the operator .
5. it should be placed at the convenient location with adjustable control switches .
6. foot switches are preferred to improve infection control.

patient positions :

patient should be seated so that all his body parts are well supported.
• the patient's head should always be supported by adjustable/ articulated headrest.
• preferably the patient's head should be in line with his back .
• the chair height should be kept low, backrest should be upright and armrest should be adjustable while making the patient to seat in the dental chair.
• now, the chair can be adjusted to place the patient in reclining position.
• patient position can vary with operator, type of procedure and area of the oral cavity.
for restorative dental procedures, the most preferred operating positions are:
1. upright position

2. almost supine
3. reclined 45 degree

- the most common patient positions for operative dentistry are almost supine or reclined 45 degrees. the choice of patient position varies with the operator, the type of procedure, and the area of the mouth involved in the operation.

chair positions :

1. **upright position :** is the initial position of chair from which further adjustments are made chair position
2. **almost supine :** in this , chair position is such that head, knees and feet are approx. at same level • patient's head should not be lower than feet except in case of syncopal attack
3. **reeclined 45 degrees :** in this position , chair is reclined at 45 degree mandibular occlusal surface are almost 45 degree to the floor .

operating positions :

- once the patient has been comfortably positioned, the dentist and the assistant should sit themselves in the proper positions for treatment. usually sitting position is preferred in modern dentistry to relieve stress on operator's leg and support the operator's back. the level of teeth being treated should be placed at same level as the level of operator's elbow.
- for better understanding, sitting positions of operator are related to a clock. in this clock concept, an imaginary circle is drawn over the dental chair, keeping the patient's head at the center of the circle. then the numbering to circle is given similar to a clock with the top of the circle at 12 o'clock.

accordingly the operator's positions

- **(right handed operator)** 7 o'clock, 9 o'clock, 11 o'clock, and 12 o'clock
- **left handed operator's positions** , 5 o'clock, 3 o'clock and 1 o'clock .

1. **right front position** (7 o'clock)

1. it helps in examination of the patient
2. working areas include:

a) mandibular anterior

b) mandibular posterior teeth (right side)
c) maxillary anterior teeth
3. to increase the ease and visibility, the patient's head may be turned towards the operator.

2. right position (9 o'clock) : in this position, dentist sits exactly right to the patient

working areas include:
a) facial surfaces of maxillary right posterior teeth
b) facial surfaces of mandibular right posterior teeth
c) occlusal surfaces of mandibular right posterior teeth.

3. right rear position (11 o'clock)

1. in this position, dentist sits behind and slightly to the right of the patient and the left arm is positioned around patient's head
2. this is preferred position for most of dental procedures
3. most areas of mouth are accessible from this position either using direct or indirect vision
4. working areas include:
a) palatal and incisal (occlusal) surfaces of maxillary teeth
b) mandibular teeth (direct vision).

4. direct rear position (12 o'clock)

1. dentist sits directly behind the patient and looks down over the patient's head during procedure.
2. working areas are lingual surfaces of mandibular teeth.
3. this position has limited application.

Right handed operator 3 preferred position	**Left handed operator 3 preferred position**
7 o'clock	5 o'clock
9 o'clock	3 o'clock
11 o'clock	1 o'clock

Consideration while donning patients :

1. while doing work in maxillary arch, maxillary occlusal surfaces should be perpendicular to the floor.
2. in mandibular arch, mandibular occlusal surface should be oriented 45° to the floor.
3. patient's head can be rotated backward or forward or from side to side for operators ease and visibility while doing work.
4. maintain proper working distance during dental procedure. this will lead to increase cooperation and confidence among the patient.
5. operator should not rest forearms on the patient's shoulders and hands on the face of the patient. considerations while doing patient .
6. dentist should not use patient's chest as instrument trolley.
7. the operator should leave left hand free during most of dental procedures for retraction using mouth mirrors or fingers of left hand.
8. operator should keep changing position if procedure is of long duration to decrease the muscle strain and fatigue.

conclusion : proper use of the chair positions as according to the relative operating areas helps the operator to complete the procedure without delayed. it also reduces the chances of causing musculoskeletal disorders.

Prevention of periodontal diseases

1. Mechanical Plaque Control :

1.Toothbrush
2. Interdental cleaning aids
A-dental floss
B- Wooden/ Rubber Tips
C- interproximal brush
3. Dentifrice

1.Toothbrush

- Tooth brushing tools date back to 3500-3000 BC when the Babylonians and the Egyptians made a brush by fraying the end of a twig .
- The Chinese are believed to have invented the first natural bristle toothbrush using pig hair and bamboo stick(handle) .

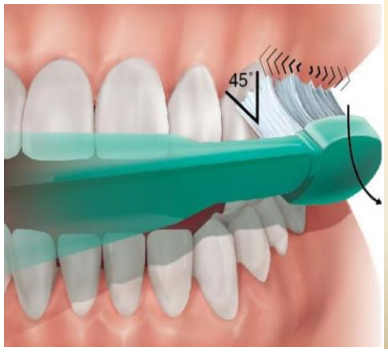
Objectives of Tooth brushing
1. To clean teeth of food, stains and debris.
2. To disturb and remove plaque formation.
3. To stimulate and message the gingival tissue.
4. To apply fluoride dentifrice.
5. Cleaning of tongue.

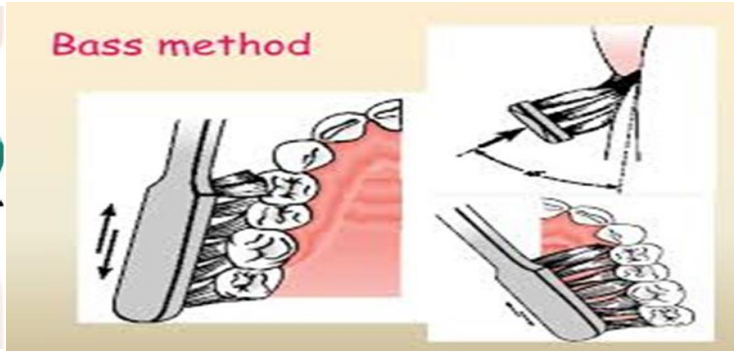
1. The Bass Method (Sulcular Brushing) :

It is widely accepted and particularly useful in removing plaque not only at the gingival margin, but also subgingivally.
Indications
1. For plaque removal adjacent to and directly beneath the gingival margin in all individuals.
2. Particularly useful in open interproximal areas, cervical areas beneath the height of contour of the enamel and exposed root surfaces.
3. Post periodontal surgery.

Procedure

The head of the brush is positioned in an oblique direction towards the apex, in order to introduce the bristles into the gingival sulcus. The bristles are about 45 degrees to the axis of the teeth. The brush is pressed towards the gingival and moved with a small circular motion so that the bristles go into the crevice. 20 strokes are completed in the same position, three teeth at a time. For occlusal surface cleaning, bristles are pressed firmly into the pits and fissures and activate the brush into 20 short back and forth strokes.





2. Stillman's Method

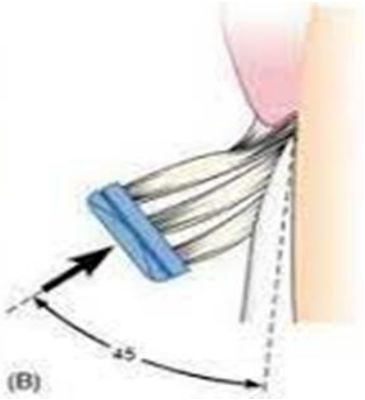
Indications

As the bristle ends are not directed into sulcus, this method can recommended for individuals with progressive gingival recession.

Technique

This method was originally developed to provide gingival stimulation. The brush is positioned with bristles inclined at a 45 degree angle to the long axis of the tooth, with the bristles placed partly on the gingiva and partly on the cervical portion of the tooth. The strokes are activated in a short back and forth (vibratory) motion, with slight pressure to stimulate the gingiva. Approximately 5 to 10 strokes are completed in each region, and the brush is moved to the next

area. Brush placement is vertical on the anterior lingual surfaces and the heel of the brush is used.



3. The Rolling Stroke

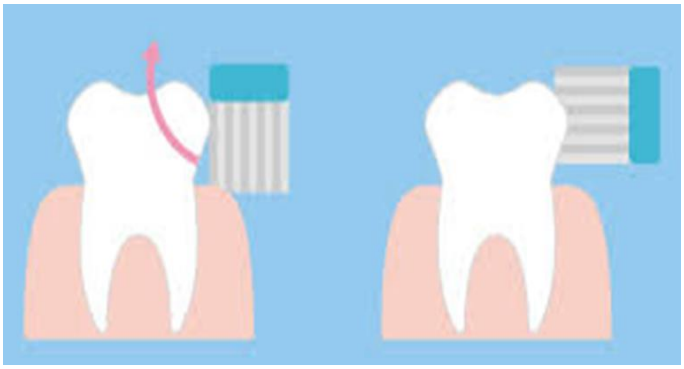
This method is used for cleaning of the gingiva and the teeth of plaque and food debris without emphasis on gingival sulcus.

Indications

1. For children with a healthy gingiva and normal tissue contour when a sulcular technique may seem difficult to grasp.
2. Used in conjunction with vibratory technique, i.e. Bass, Stillman's, or Charter's.

Technique

Bristles are directed apically and parallel to the axis of the tooth. The brush is then rotated deliberately down in the upper jaw and upward in the lower jaw so that, bristle sweep across the gum and tooth in an occlusal direction with rolling motion. If the arch in the anterior segment is narrow the brush can be used vertically.



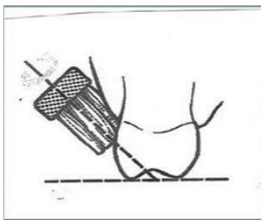
4. Charter's Method

Purpose and Indications

1. Massage and stimulate marginal and interdental gingiva
2. Cleaning of orthodontic appliances.
3. Cleaning following periodontal surgery.
4. Fixed prosthetic appliances.
5. Person with exposed root surfaces.
6. Cases with receded interdental papillae.

Procedure

In this technique the bristles are pointed towards the crown of the tooth rather than apically. The bristles are placed at the gingival margin and directed towards the occlusal surface at a 45 degree angle to the long axis of the tooth. A short back and forth motion is used for activation. The process is repeated in a sequence around the mouth until all areas are cleaned.



5. The Fones Method (Circular) :

This method may be recommended as an easy to learn technique for young children.
Indication : young children with primary teeth; otherwise not recommended.

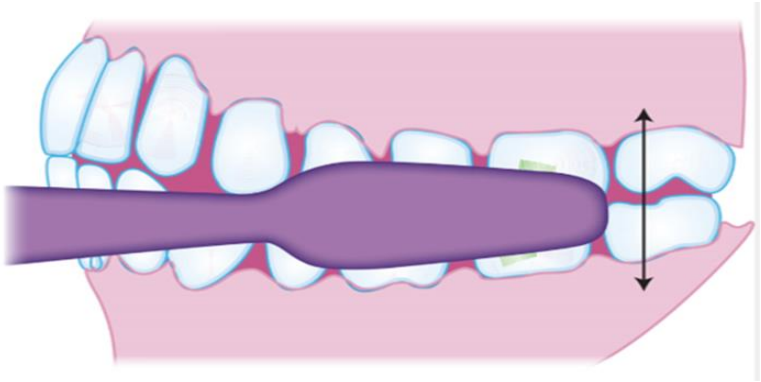
Technique

The brush is placed inside the mouth. With the teeth closed and brush tips contacting the gingiva over the last maxillary molar, bristles are activated in circular motion that sweeps from the maxillary gingiva to the mandibular gingiva.

6. Vertical(Leonard Method) :

Technique

With the teeth edge-to-edge, place the brush with the filaments against the teeth at right angles to the long axis of the teeth. The brush is activated with mostly up and down strokes on the tooth surface. The upper and lower teeth are not brushed in the same series of stroke. This technique is usually not recommended.



7. Physiologic(Smith's Method) :

It was described by Smith. It was based on the principle that the tooth brush should follow the same physiologic pathway that food follows when it traverses over the tissues in a natural masticating act.

Technique

The toothbrush bristles are positioned at the incisal or occlusal surfaces and are swept towards the gingiva. The direction of the brushing motion from the occlusal to the gingiva was like duplicating the nature's self cleansing mechanism.

8. Scrub Brush Method

It is probably the most commonly used toothbrushing method. The procedure consists of vigorously combined horizontal, vertical and circular strokes with some vibratory motions for certain areas.

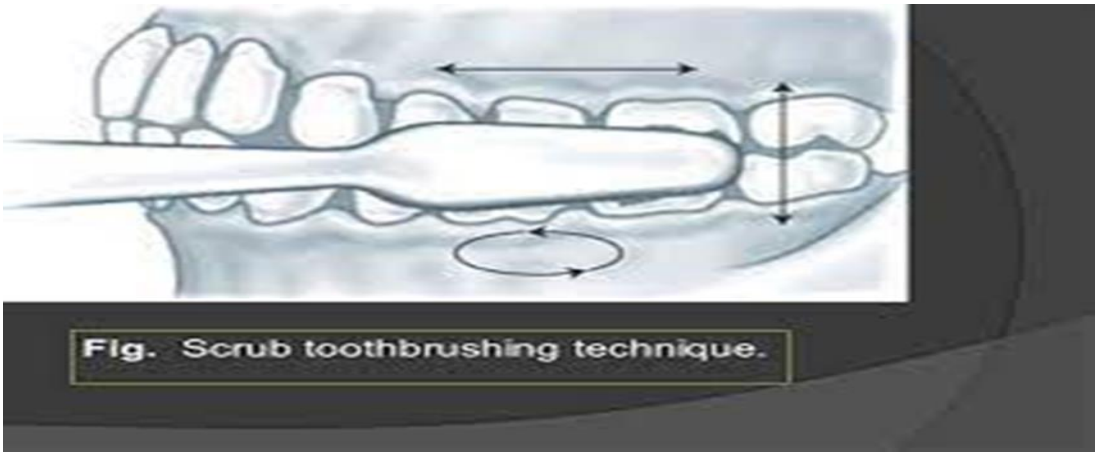


Fig. Scrub toothbrushing technique.

2. Interdental cleaning aids

- The majority of dental and periodontal disease's originate in interproximal area.
- Tissue destruction associated with periodontal often leave large, open spaces between teeth and exposed roots with anatomic concavities and furcations which are difficult to clean and access with toothbrush.

A-dental floss

Most widely recommended method for removing proximal plaque .

Types of Dental Floss

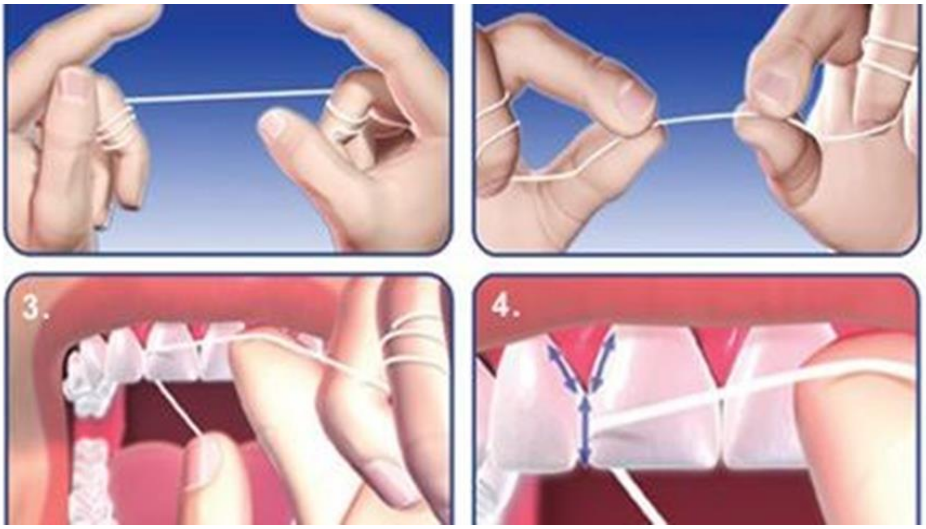
1. Twisted or non-twisted.
2. Bonded or non-bonded.
3. Waxed or un-waxed.
4. Thin or thick.

Methods of Using Dental Floss :

1. Spool method ; It is recommended for teenagers and adults who have acquired the required the level of neuromuscular coordination and mental maturity to use floss correctly.

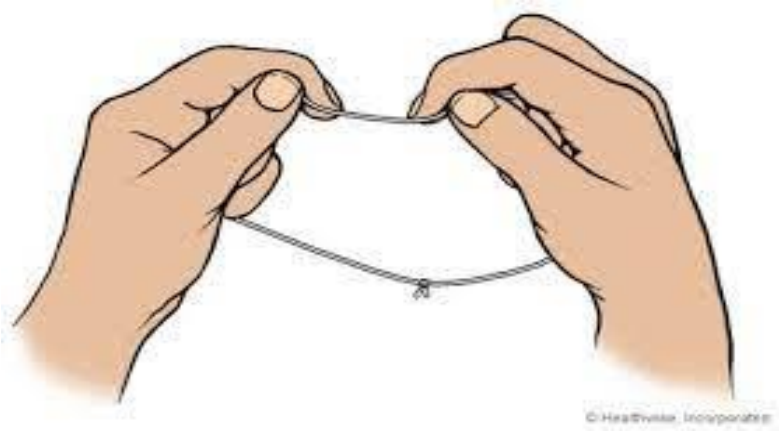
Method :

- Cut off a piece of floss approximately 18-20" in length
- Wind each end around your middle finger several times
- Using your thumbs and index fingers, guide the floss in between teeth in an up-and-down motion toward the gum line
- When you are flossing correctly, the string should form 'C' around each tooth.



2. Loop or circle method ; This method is particularly suited for children as well as adults with less nimble hands or handicaps such as poor muscular coordination or arthritis.

Method:
Use a piece of floss about 30 cm (12 in.) long .
Tie the ends together, forming a loop. If the loop is too large, wrap the floss around your fingers to make it smaller.
Gently work the floss between the teeth toward the gums. Curve the floss around each tooth into a U-shape, and gently slide it under the gum line .
Move the floss firmly up and down several times to scrape off the plaque.



B- Wooden/ Rubber Tips

1. Wooden tips

- Used either with or without a handle
- Access is easier from the buccal surfaces for those tips without handles, primarily in the anterior and bicuspid areas.

Disadvantage- It is very hard to access surfaces other than the facial surfaces in the more anterior region of the mouth. Only used in large gingival embrasure

2. Rubber tips : Usually mounted on handles or the ends of toothbrushes and can easily be adapted to all proximal surfaces in the mouth.

C- interproximal brush

Cone-shaped or cylindrical brushes made of bristles mounted on a handle

Method:

- Inserted through interproximal spaces and moved back and forth between the teeth with short strokes.
- For most efficient cleaning, select the diameter of brush that is slightly larger than the gingival embrasures to be cleaned

3-Dentifrice

A dentifrice is usually used in combination with tooth brushing with the purpose of facilitating plaque removal and applying preventive and therapeutic agents to the tooth surfaces. A toothpaste is defined as a semi-aqueous material for removing naturally occurring deposits from teeth and is supposed to be used simultaneous with a toothbrush. The dentifrice can either be: Cosmetic which cleans and removes material alba, plaque biofilm, food debris and stains from tooth surfaces and polishes. Therapeutic which transports the drug substance to the tooth surface or the oral tissue.

Deciduous teeth

Primary Dentition

These are the first teeth to erupt into the oral cavity. The primary dentition is comprised of 20 teeth. These teeth will be exfoliated (lost) as the permanent teeth erupt.

- Primary teeth are also called as temporary , milk , deciduous or baby teeth.
- Significant differences in different aspects distinguish them from their permanent counterparts.
- Primary teeth are essentially placeholders for permanent teeth, but they differ in composition, structure, and number.
- Children begin losing their primary teeth around age 6 and should have 28 permanent teeth by age 13.
- Molars, commonly known as “six-year molars,” are the first teeth to erupt in children, around age 6.
- Good oral care is important for primary and permanent teeth .
- The first primary teeth to erupt are usually the lower central incisors .Although there is natural variation, the average age for eruption is seven months. Occasionally, one or more teeth may be present at birth, or erupt in the first month of life. These teeth, which tend to be in the lower incisor region, may be part of the primary dentition or anomalous tooth-like structures. Natal teeth, which do not form part of the primary dentition, may need to be extracted if there is a danger of detachment and inhalation, difficulties in feeding or ulceration of the undersurface of the tongue (see ‘Photo guide: tooth eruption in children’).
- The deciduous teeth important for phonetics , esthetics , allow proper mastication , prevent malocclusion and guide the eruption of permanent teeth.

Estimation of dental age :

1. To evaluate general health distribution .
2. To know the age of foreign children .
3. In forensic dentistry , to know the victim .

Eruption Sequences

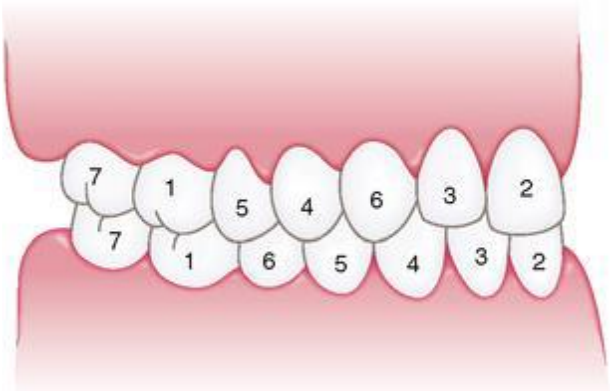
Eruption sequence for primary teeth follows a pattern – incisors-first molars-canines-second molars. ′ This pattern is generally followed by both arches, with the mandibular arch preceding the maxillary arch. ′ The loss of deciduous teeth tends to mirror the eruption sequence. ′ Caries susceptibility is reverse of this order.

For primary teeth

	ABDCE
	ABDCE

For permanent teeth:

	61245378
	61234578



Primary dentition :

Age	Crown development starts	Crown fully formed	Eruption
3-6 m. in utero	A , B , C , D , E		
3-6 m. after birth		A , B , D	
6-9m.		C	A , B
1 year		E	D
1½ year			C
2-2.5 year			E

Permanent dentition :

Age	Crown developments starts	Crown fully formed	Eruption
Birth – 6 month	6 , 1 , 2 , 3		
3 years	4 , 5 , 7	6 , 1 , 2	
6 years		4 , 5 , 7 , 3	6 , 1 , 2
9 years			3 ⌐
12 years			4 , 5 , 7 , ∟3

The roots of deciduous teeth are fully formed after eruption , then resorption of these roots starts until exfoliation of the deciduous teeth occurred , followed by eruption of the permanent teeth .
In the eruption of deciduous teeth , there were no differences in the time of eruption in gender , while the lower teeth erupt earlier than upper teeth .while in the permanent teeth , girls earlier than boys , and lower teeth earlier than upper teeth .

Anatomical And Morphological Difference between Primary And Permanent teeth :

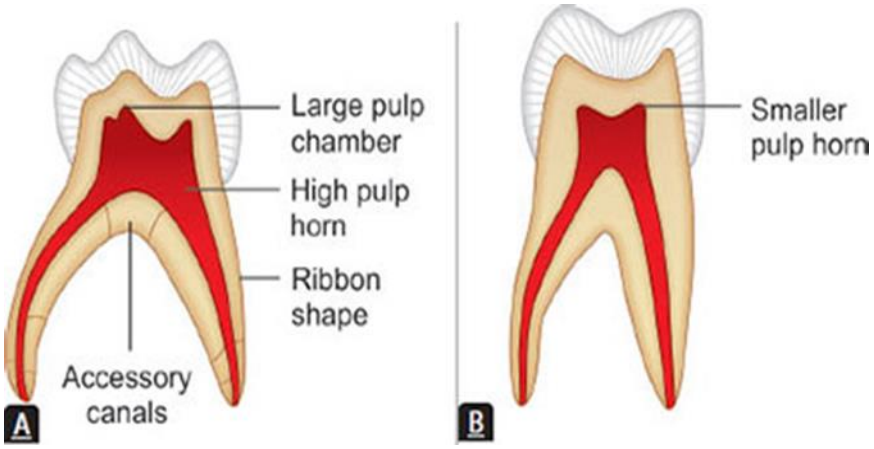
- General Differences
  1. No. of teeth present:- primary (20) , permanent (28-32) .
  2. Bicuspids and third molars are absent in the primary set of tooth.
  3. Primary teeth are smaller in size when compare to permanent teeth.
  4. 1st tooth to erupt into the oral cavity is mandibular incisor whereas in permanent teeth it is the mandibular first molar.
  5. Primate space is absent in permanent teeth.

- Primate space is **a naturally occurring spacing between deciduous teeth**. In the mandibular arch, the primate space is observed between primary canine and first molar. The primate space in the maxillary arch is located between primary lateral incisor and canine.

- **Differences in the crown , pulp and root :**
- **Crown**
- Primary Teeth Crown: shorter , narrow occlusal table , constricted in cervical portion. thinner enamel and dentin layers . color is usually lighter. prominent mesio-buccal cervical bulge seen in primary molars. incisors have no developmental grooves or mammelons.
- Permanent teeth crown: bigger , broad occlusal table, cervical constriction is not well marked. thick enamel and dentin layer, color is much darker. permanent teeth have less prominent cervical bulge seen in permanent molars. incisors have developmental grooves or mamelons on newly erupted teeth

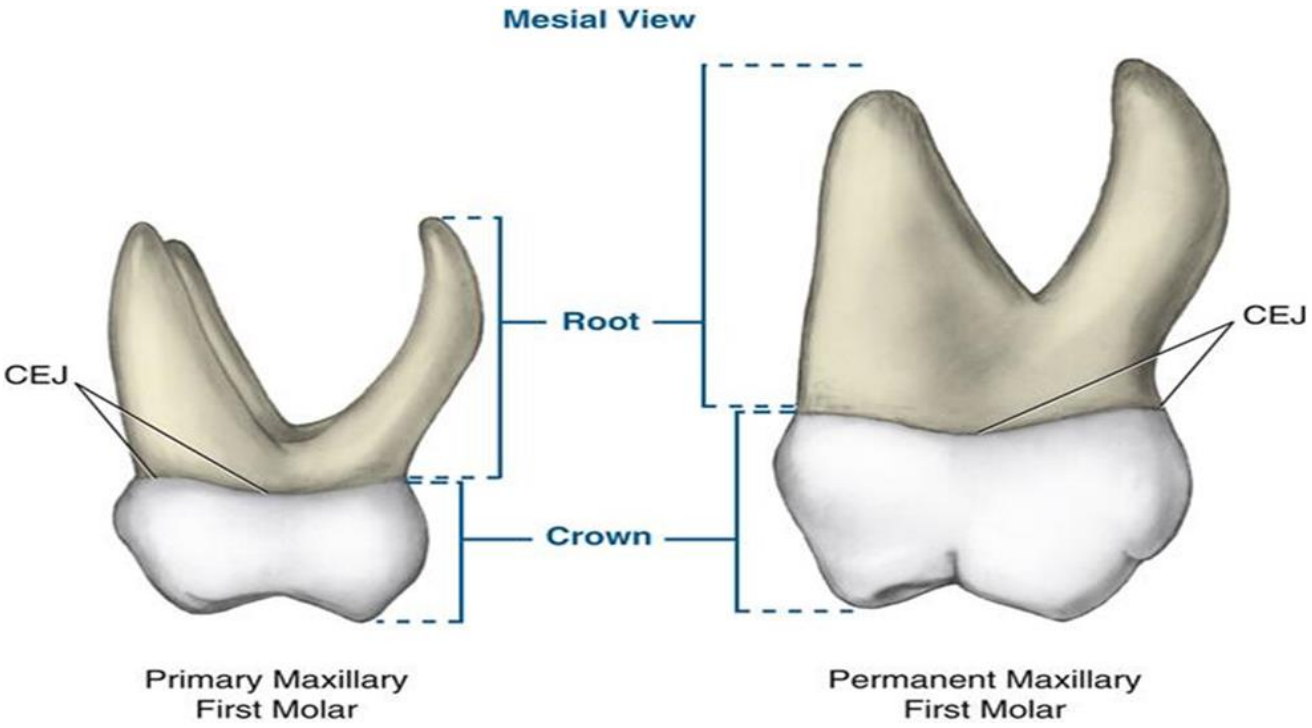
- **Pulp :**

1. **Primary teeth :** pulp chamber is larger in relation to crown size. pulp horns are closer to the outer surface. mesial pulp horn extends to a closer approximation of surface than the distal pulp horn. high degree of cellularity and vascularity in tissue. comparatively less tooth structure. root canals are more ribbon like. the radicular pulp follows a thin , tortuous and branching path.
2. **Permanent teeth :** pulp chamber is smaller in relation to crown size. the pulp horns are comparatively away from the outer surface. ′ comparatively less degree of cellularity and vascularity in tissue. .more tooth structure protecting the pulp. ′ comparatively lesser thickness of dentin over the pulpal wall at the occlusal fossa of molars. root canals are well defined with less branching.



- **Root :**

Primary teeth : Roots are larger and more slender in comparison to crown size. Furcation is more towards cervical area so that root trunk is smaller . Roots are narrower mesio-distally. Undergo physiologic resorption during shedding of primary teeth.
Permanent teeth : Roots are shorter and bulbous in comparison to crown. Placement of furcation is apical , thus the root trunk is larger. Roots are broader mesio- distally. Physiologic resorption is absent.

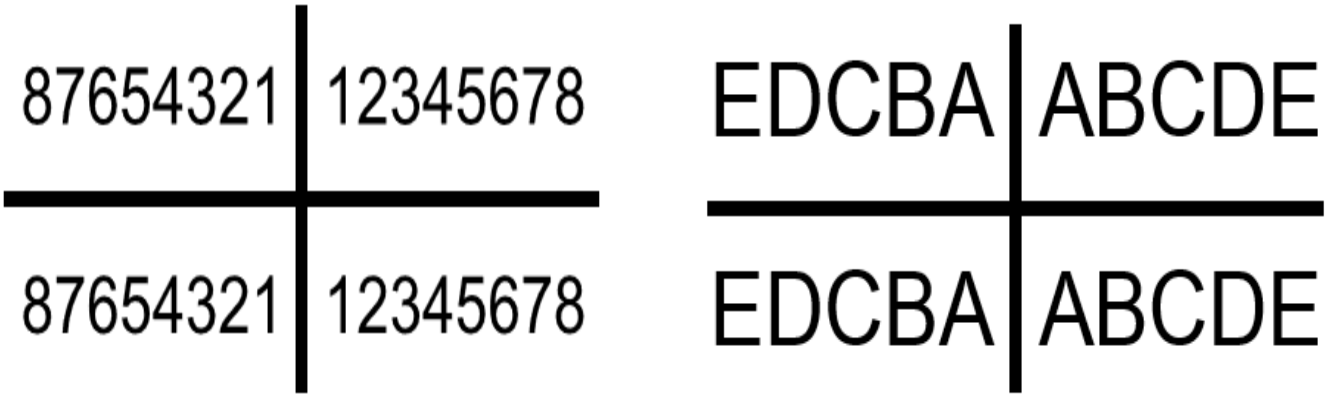


Tooth numbering system

1. Zsigmondy- palmer system

The Hungarian dentist Adolf Zsigmondy discovered this system in 1861, using a Zsigmondy cross to record quadrants of tooth positions. Adult teeth were numbered 1 to 8, and the child primary dentition (also called deciduous, milk or baby teeth) were depicted with a quadrant grid using Roman numerals I, II, III, IV, V to number the teeth from the midline. Palmer changed this to A, B, C, D, E. This makes it less confusing and less prone to errors in interpretation.

The Palmer notation consists of a symbol (┘ └ ┐ ┌) designating in which quadrant the tooth is found and a number indicating the position from the midline. Adult teeth are numbered 1 to 8, with deciduous (baby) teeth indicated by a letter A to E. Hence the left and right maxillary central incisor would have the same number, "1", but the right one would have the symbol, "┘ ", underneath it, while the left one would have, " └".



Advantages:

1) Easy to implement.

2) Easy of writing and communication.

3) Less mistakes in identifying the designated tooth.

Disadvantages:

1) Cannot be written by the computer.

2) Non-numeric symbolization.

2. Universal numbering system

This tooth numbering system was proposed by German dentist Julius Parredidt in 1882. Although it is named the "universal numbering system", it is also called the "American system" as it is commonly used in the United States. The uppercase letters A through T are used for primary teeth and the numbers 1 - 32 are used for permanent teeth. The tooth designated "1" is the maxillary right third molar ("wisdom tooth") and the count continues along the upper teeth to the left side. Then the count begins at the mandibular left third molar, designated number 17,

and continues along the bottom teeth to the right side. Each tooth has a unique number or letter, allowing for easier use on keyboards. As specific numbers are employed for each tooth, it reduces the risk of mistake. Data can also be easily entered in the computer.

Permanent Teeth															
Upper Right								Upper Left							
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17
Lower Right								Lower Left							

Primary teeth									
Upper Right					Upper Left				
A	B	C	D	E	F	G	H	I	J
T	S	R	Q	P	O	N	M	L	K
Lower Right					Lower Left				

Advantages –

1. Individual number for each tooth**.** 2. Simple

Disadvantages:

1. Difficult in remembering the tooth no.

2. Matching the specific teeth and quadrants can be confusing.

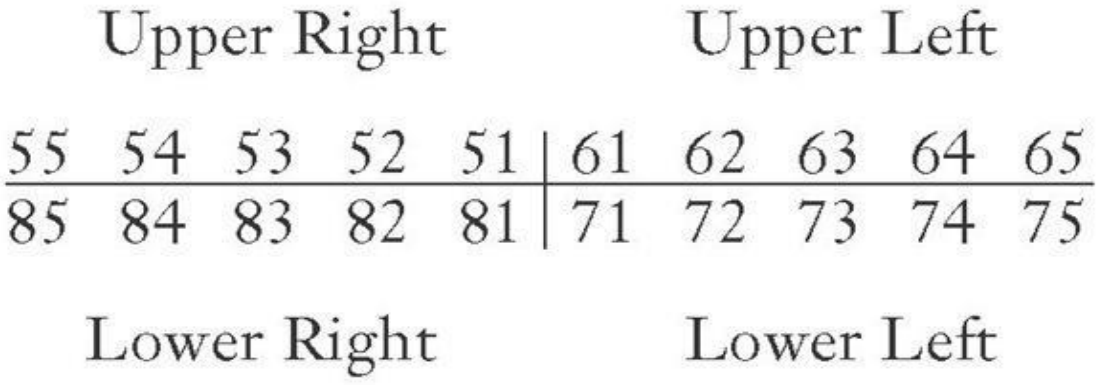
3. There is no anatomic reference in this system and so it is difficult to follow for the beginners, and needs extra training to practice.

3. International numbering system

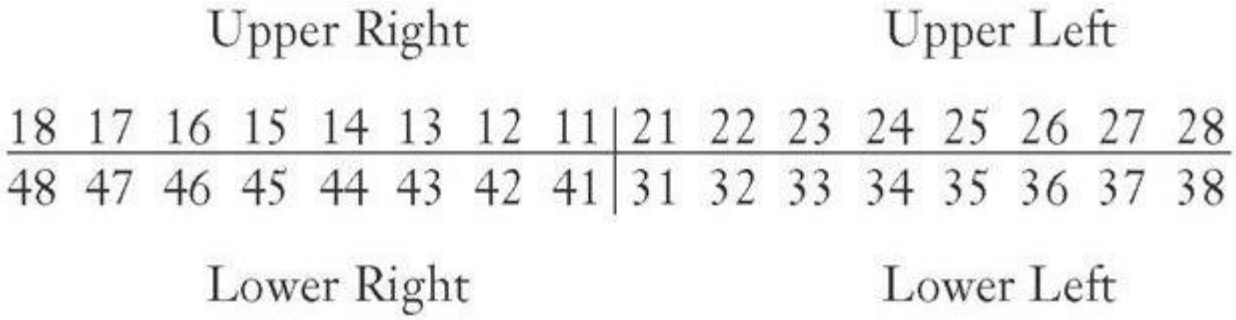
The Federation Dentaire Internationale (FDI) system is a two-digit system, the first digit indicates the quadrant (1 through 4 for permanent and 5 through 8 for deciduous teeth) and the second digit indicates the tooth type (1 through 8 or 1 through 5). It is very simple, accurate, it is easy to memorize in the visual and cognitive sense, it is user friendly, and prevents errors in differentiating left and right, upper and lower arches, and tooth type. However, in the case of deciduous teeth, there can be confusion and it is difficult to memorize. For specialists other

than paedodontists, it can be difficult to understand or to define teeth, as in the case for example of 64, 85.

PRIMARY TEETH :



PERMANENT TEETH :



Advantages:

Easy to remember and understand

Unique number for each tooth

Verbal communication is possible

Compatible with computer keyboard

Hence most accepted.

Community Dentistry

Dr. Hind Thyab

Occupational Hazards in Dentistry

In carrying out their professional work, dentists are exposed to a number of occupational hazards. These cause the appearance of various ailments, specific to the profession, which develop and intensify with years. In many cases they result in diseases and disease complexes, some of which are regarded as occupational illnesses.

DEFINITION :

Occupational hazard can be defined as a risk to a person usually arising out of employment. It can also refer to a work, material, substance, process, or situation that predisposes, or itself causes accidents or disease, at a work place.

Who is at risk ???

All dental healthcare professionals are potentially affected , including :

- The dentist .
- Auxiliary dental workers (nurses , therapist , hygienist) .
- Other at place of the work (service) .

Major occupational hazards are:

1. Biological health hazards
2. Physical hazards
3. Chemical hazards
4. Musculoskeletal disorders and diseases of the peripheral nervous system
5. Hearing loss
6. Radiation exposure
7. Stress
8. Legal hazards
9. Other risks

Biological Health Hazards : These hazards are constituted by infectious agents of human origin and include viruses, bacteria and fungi. All members of the dental team are at risk of exposure to hepatitis B virus

(HBV), HIV infection, and other types of communicable infections. Several of the common viral agents that can cause hepatitis have been detected in body fluids including saliva and blood. The viruses most commonly implicated include hepatitis A virus (HAV), HBV, and hepatitis C. A dentist can become infected either directly or indirectly.
In the first case, microorganisms can pass into organism, through a cut on the skin of his/her hand while performing a medical examination, as a result of an accidental bite by the patient during a dental procedure, or through a needle wound during an anesthetic procedure. Indirect infection sources include: Aerosols of saliva, gingival fluid, natural organic dust particles (dental caries tissue) mixed with air and water, and breaking free from dental instruments and devices. The following are the main entry points of infection for a dentist: epidermis of hands, oral epithelium, nasal epithelium, epithelium of upper airways, epithelium of bronchial tubes, epithelium of alveoli, and conjunctival epithelium.

Physical Hazards : The dentist and the clinical staff are at risk of physical injuries during many dental procedures. Sources of physical injury can include debris from the oral cavity striking the eyes, cuts from sharp instruments, or puncture wounds from needles or other sharp instruments. Such injuries can result in the transmission of serious infectious disease to the dental worker. Percutaneous exposure incident (PEI) is a broad descriptive term that includes needlestick and sharp injuries, as well as cutaneous and mucous exposures to blood and serum. The most common of them is from needles and drilling instruments such as burs. From the occupational viewpoint, PEI represents the most efficient method for transmitting blood borne infections between patients and health care workers. Eye injuries may occur from projectiles such as bits of calculus during scaling procedures and splatters from body fluids (bacterial and viral aerosols) while using high-speed hand pieces. Another potential source of eye injury is the intense dental curing light. Users of dental curing lights should be advised to employ protective eyewear during use. The use of protective eyewear is an important means of preventing occupational injury related to the use of dental curing lights and high-speed rotary instruments. Injury from splatters and projectiles including calculus and flying debris during cavity preparation is a common cause of damage to the eyes, and the use of protective eyewear should be emphasized.

Chemical Hazards : The chemical environment is one of the most rapidly expanding components of the work environment because new chemicals and solutions are being introduced regularly. Many of these chemicals are among those whose health effects may not be known and may pose health problems taking years to manifest. Many biomaterials and auxiliary products used in dentistry are chemically reactive. Hazardous chemical agents used in clinical dentistry include mercury, powdered natural rubber latex (NRL), disinfectants, and nitrous oxide (N2O). By far the most important and most dangerous of these agents is mercury.

Musculoskeletal Disorders and Diseases of the Peripheral Nervous System : At work, the dentist assumes a strained posture (both while standing and sitting close to a patient who remains in a sitting or lying position), which causes an overstress of the spine and limbs. The overstress negatively affects the musculoskeletal system and the peripheral nervous system; above all, it affects the peripheral nerves of the upper limbs and neck nerve roots. The posture of the dentist at work, with the neck bent and twisted, an arm abducted, repetitive and precise movements of the hand, are a frequent cause of the neck syndrome and of pain within the shoulder and upper extremities. Operations carried out during extractions stress not only the elbow joint and the wrist joint but may result in chronic tendon sheath inflammation. The long-term effect of all those adverse circumstances occurring in the work of the dental doctor may lead to diseases described as cumulative trauma disorders. The most common injuries reportedly experienced by the dental hygienist are musculoskeletal in nature. The need to work in a fixed working position using a continuous repetitive motion can predispose the clinical dental worker to wrist-ache, lower backache, and neckache.

Hearing Loss : The noise of suctions, saliva ejectors, turbines, engines, amalgamators, compressors, etc. may causes impaired hearing. The noise levels of modern dental equipments have now generally fallen below the risk of hearing loss . Still some dentist may be at risk specially where faulty or older equipment is used.

Radiation exposure : Exposure to both ionizing and nonionizing radiation may occur in dental practice. During an average radiological examination, the radiation dose received by an individual is generally low and relatively few cells are damaged. Though cellular repair is expected, it is not necessarily perfect. Thus, the effect of even low levels of exposure to ionizing radiation over periods of time may accumulate and could represent a potential hazard to health.

Stress : Stress is the most common psychological condition that occurs in the dental profession. Stress situations form an inherent part of a dentist's everyday work. Although seldom discussed, they should be considered in view of the hazards connected with this profession, a profession which requires that a dentist should act in two roles: as a psychotherapist and a manually skilled operator. Many clinical situations are the source of stress to a dentist and these include, among others, procedures connected with anesthetization of patients, overcoming of pain and fear, unexpected emergency situations in which a patient's health or life is in danger, or procedures with uncertain prognosis. The following factors, such as the necessity to keep a proper professional standard, aspiration to achieve technical perfection, causing pain or fear in patients, the necessity to cope with cancelled visits or late arrivals by patients, having to cope with different levels of cooperation with patients, are some of the very important sources of stress in everyday dental practice.

Legal Hazards : In every country there are relevant statutes and regulations which apply to the practice of dentistry. The contravention of any of these may warrant that legal actions be brought against a dental practitioner particularly in developed countries where the citizens appear more aware of their rights. To help assure a safe work environment in dental treatment, the hazard awareness and prevention of legal risks should be made known to all clinical workers of the dental hospital/clinic.

Other Risks : Mild neuropathy among dental professionals has been shown to be associated with high frequency vibrations from dental equipments, particularly high and low speed handpieces and ultrasonic scalers.

Prevention of Occupationl Hazards

Health risks in dentistry may arise as new technologies and materials are developed. However, once identified and recognized as risk, new guidelines, precautions, and protocols are often rapidly instituted to greatly reduce or even eliminate the occupational hazard. Education is one of the important strategies for the prevention of occupational injuries and diseases. Concerning prevention, the international literature focuses mostly on infection control and proper handling of potentially infected materials, owing to the high profile of dentistry regarding transmission of infection. Barrier techniques include gloves, masks, protective eye wear, high power suction and good ventilation to reduce aerosols and vapor dangers. Hypoallergenic nonlatex gloves are proposed to deal with latex allergy. Lead aprons, periodic maintenance of the X-ray machine and radiation level sensors prevent radiation hazard.

Forensic Dentistry

Forensic dentistry, or forensic odontology, is the application of dental and para dental knowledge to the solution of legal issues in civil and in criminal matters. Dentition and finger prints form the most scientifically reliable identification methods due to their individuality (the uniqueness of individual's dentition) and specificity. Dental identification , like fingerprint identification, is a definitive means of positive identification of unknown human remains .

Constituents of Forensic dentistry

Forensic odontology mainly constitutes the following headings:
1. Postmortem dental identification and disaster victim identification.
2. Age estimation.
3. Anthropology.
4. Bite mark analysis.

Forensic dentists are responsible for six main areas of practice:

1. Identification of found human remains.
2. Identification in mass fatalities.
3. Assessment of bite mark injuries.
4. Assessment of cases of abuse (child, spousal, elder).
5. Civil cases involving malpractice
6. Age estimation.

Means of Identifications in Forensic Dentistry:

1. Teeth: Natural and synthetic (fixed and removable)
2. Bone: Trabecular pattern, tori and osseous anomalies
3. Presence of foreign bodies: Implants, amalgam particles, surgical instruments, bullets, fragments of various origins
4. Sinus configuration: Maxillary and frontal
5. Skull sutures
6. Soft tissue features: Rugae and lip prints.
7. Photographic comparison: Facial or dental superimposition or approximation
8. DNA.

Role Of Teeth In Determination Of Human Identity Important Of Dental Identification

Dental evidence tends to survive much better than does soft tissue evidence such as facial characteristics or fingerprints. Teeth are calcified structures and are the

hardest substance in the human body, even harder than bone. Because they are calcified, they are resistant to the environmental effects that destroy soft tissue evidence. Thus teeth are not destroyed by immersion in water, by desiccation (drying up), or by decomposition In addition, the dental restorations are frequently completely intact.

Application of Forensic Dentistry:

The dentist may help with problem involving →

1. Ageing. Determination of age:
   - In children→ concerning with the pattern of teeth eruption, root length(degree of completion of roots erupted teeth and resorption of roots of deciduous teeth). Teeth wear.
   - In young adults → development of wisdom (third molar).
   - Older adults →include parameters like attrition, gingival recession periodontal disease progression multiple fillings and complex restorative work, extractions ,formation of physiological secondary dentine, formation of cementum.
2. Gender. Determination of gender can be assessed from:
   - Teeth shape (no gender differences regarding teeth morphology).
   - Skull shape and form ; the male skull tends to be larger, have a lower, sloping forehead, larger muscle attachment sites and smaller, squarer eye sockets when compared to females.
   - Development and eruption of teeth (teeth eruption is accelerated in early maturing girls)
   - Mandibular canines size (the mesiodistal width of canines of both the jaws is significantly greater in males than females) .
3. Race: can be assessed from skull shape and form, anatomical characterization,cusp numbers, grooves and pattern of molars, such as Carabilli cusp, Leong's premolar(6 and 7 cusp),shovel - shaped incisors.
4. Socio-economic status and geographical factors: Endemic fluorosis, dental caries and type of dental restorations.

Bite marks:

Dental evidence most commonly used in the criminal court is the bite marks, which provide details of a kind comparable with infinitive detail that was provided by finger prints Bites are common in violent crime and child abuse. **Bite marks** is defined as" a mark made by teeth alone or in combination with other oral structure", bite marks can be found on:

- The victim(by the attacker)
- The attacker(suspect) when a victim attempts to defend himself
- An object found at the crime scene.

The physical characteristics of both the bite mark wound and the suspect's teeth include:

- The distance from cuspid to cuspid

• The shape of the arch
• The evidence of a tooth out of alignment
• Teeth width and thickness, spacing between teeth
• Missing teeth
• The curves of biting edges
• Unique dentistry
• Wear patterns such as chips or grinding.

Factor that may affect the accuracy of bite mark Identification include:

✓ The effects of where the bite mark was found.

✓ The damage on soft tissue.

✓ The time dependent changes on the bite mark on living bodies.

✓ Poor in technique of bite mark.

Dental Identification: dental identification help in person identification includes:

- Dental restorations→ types, their outline, unusual fracture**s of** design of filling, also root canal therapies, rehabilitation.
- Dental prosthesis. Denture found in the mouth or in the scence of activity are useful aid in identification.
- Palatine Rugae . the shape and the form of rugae is highly variable between people.It can be recorded by means of dental impression and casts made from them.
- Lip print. Lip prints are unique to the individual in a manner similar to finger prints .
- Dental DNA. The suspect's DNA profile obtained from saliva or blood of bite mark area and it's surrounding proves a more reliable form of identification.

Community Dentistry

Dr. Hind Thyab

Epidemiological studies

Epidemiological studies are required to measure the rates of disease occurrence and the associated factors in a population, to make an unbiased comparison of those with or without a disease or risk factor and to make interventions.
Epidemiological studies can be classified as :

1. (Non-experimental Observational): in these studies the investigator measures but does not intervene , There are two types of non-experimental designs.

- Analytical studies .
- Descriptive studies.

A. Descriptive Studies : they are the first phase of an epidemiological studies . These studies involve the systematic collection, analysis and interpretation of data to give a clear picture of a particular situation. The main purpose of this study is to describe the occurrence and distribution of the disease with respect to the time , place and person .

1.Cross-sectional study (prevalence study) :

This study measures the prevalence of disease and was called prevalence study . It is based on a single examination at one point in time . In this study the measurement of exposure and effect are made at one time . It tells about the distribution of disease rather than its etiology and provides little information on the natural history of the disease . Data from cross-sectional surveys are helpful in assessing the health care needs of populations .

Advantages of Cross Sectional Studies

1. Can be done in a short time.
2. Are less costly.
3. Provide a wealth of data that can be used in health systems research.
4. May be used in examining and identifying risk factors for acute diseases where the time between exposure and outcome is very short.

5. Useful for monitoring control programs for chronic conditions such as mental illness.

2.Longitudinal study (incidence study) :

In this study repeated examinations are made on the same population over a prolonged period of time in the form of follow-up examination . It is used to study the natural history of disease , for identifying the etiology and risk factors of the disease and for finding out incidence rate .

B.Analytical Studies : It is the next step in an epidemiological study . The term 'analytical' implies that the study is designed to establish the cause of a disease by looking for association between exposure to a risk factor and disease occurrence.

- The most common designs of analytical studies are :

1.Case-control studies (retrospective study) : Case control study is useful as a first step when searching for a cause of an adverse health outcome. This hallmark of this type of study is it compares a case group (with disease) with a control group (not diseased) with reference to past exposure to possible risk factors.

2.Cohort study (follow-up or incidence study) : it is also called as prospective study . These studies begin with a group of individuals (a cohort) free from the disease who share a common characteristic or experience within a defined time period , then grouped as per their exposure or non – exposure to a suspect causative factor and then monitored over a period of time for the development of disease .

3. Ecological studies (correlational study) :

In this study , the units of analysis are populations or groups of people rather than individual .

2. Experimental studies (Interventional Studies) :

In contrast to observational studies, where the epidemiologist takes no action but only observes the natural course of events or outcome, experimental studies involve some action, intervention or manipulation such as deliberate application or withdrawal of the suspected cause or changing one variable and the causative chain in the experimental group while making no change in the control group and observing and comparing the outcome of the experiment in both the groups.

The type of experimental study can take one of three forms:
- Randomized Controlled trial
- Field trial
- Community trial.

A. **Randomized Controlled trials :** A clinical study in which participants are randomly (by chance) assigned to either an experimental group or control group . The experimental group receives the new intervention and the control group receives a placebo or standard intervention . these group are followed for the outcome of interest which could be the development of a new disease or recovery from established disease .

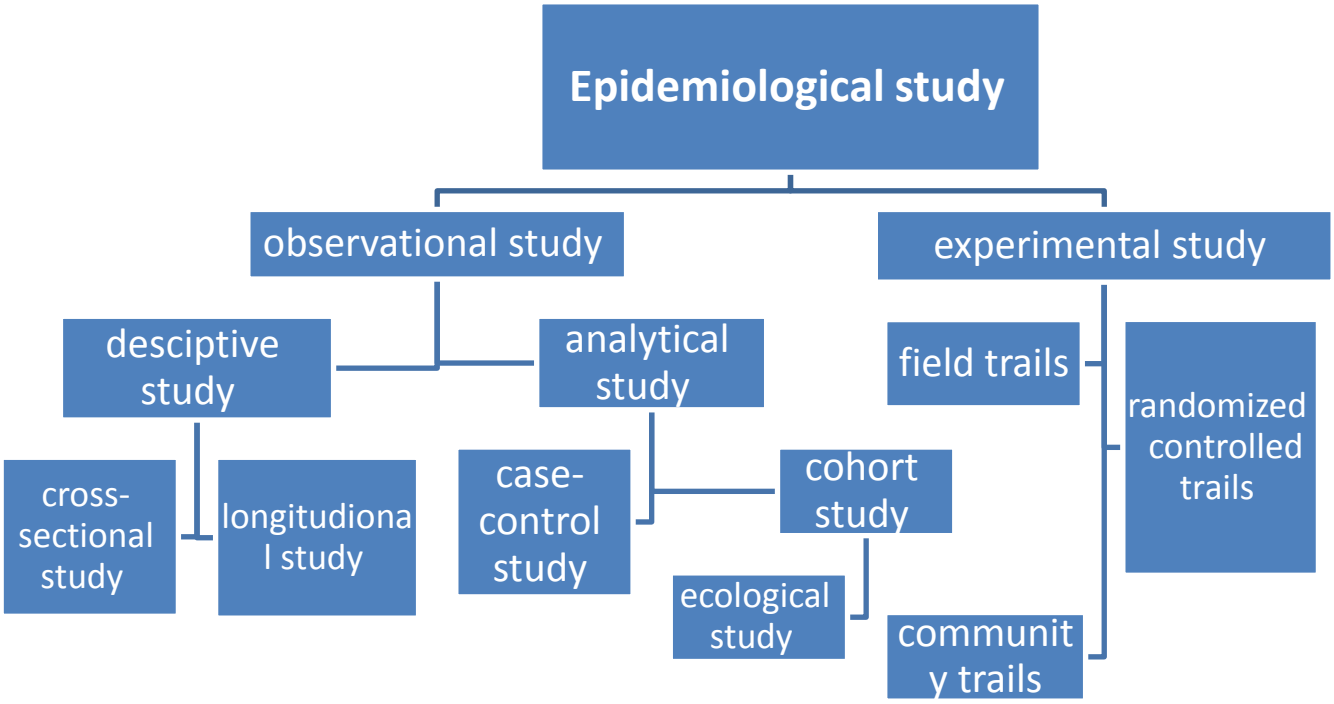
Randomization:
It is a statistical procedure by which the participants are allocated into groups usually study and control groups, to receive or not to receive an experimental preventive or therapeutic measure, procedure or intervention.

Blinding:
Is a procedure done to reduce the bias which may occur due to errors from assessment of the outcome. The subjects need to participate without knowing which type of intervention is being done on them.
Blinding is of three types
1-**Single blind trial**: The trial is planned in such a way that the participant is not aware whether he belongs to the study group or control group.

2-**Double blind trial**: The trial is so planned that neither the investigator nor the participant is aware of the group allocation and the treatment received.
3-**Triple blind trial**: The trial is planned in such a way that the participant ,the investigator and the person analyzing the data are all blind.

B. **Field trails :** These trials involve people who are disease free but are presumed to be at risk, data collection takes place in the field . Since the subjects are disease free and the purpose is to prevent the occurrence of disease that may occur with relatively low frequency , field trails are often huge undertakings involving major logistic and financial considerations .

C. **Community trails :** In this type of field trial the intervention is done on a community wide basis rather than individuals. Due to practical difficulties only a small number of communities are included. Random allocation of communities may not be feasible. These studies are appropriate for diseases that have origins in social conditions which can most easily be influenced by intervention directed at group behavior as well as at individuals.



Epidemiological study
observational study
experimental study
desciptive study
analytical study
field trails
randomized controlled trails
cross-sectional study
longitudional study
case-control study
cohort study
ecological study
community trails

Dental auxiliary and Dental man power in dental clinic

Dental auxiliary : is a person who is gives responsibility by a dentist (generic term for all persons who is assist the dentist in patient management render dental care), the duties undertaken by dental auxiliaries range from simple task (sorting instrument) to complex procedure which form part of treatment of patients, they play an important role in the public dental health.

A dentist is a person licensed to practice dentistry under the law of the appropriate state, province, territory or nation. Dentists are concerned with the prevention and control of the diseases of the oral cavity. They are legally entitled (licensed and registered) to treat patients independently, prescribe certain drugs and to employ and supervise auxiliary personnel.

World Health Organization (WHO) can classify dental auxiliary according to:

a. The training they have received.

b. The task they are expected to undertake.

c. Legal restrictions placed upon them.

Classification:

1. Non-operating auxiliaries. According to revised classification of non-operatory auxiliary are:

- **Dental surgery assistant:**

The duties of the dental assistant are

- ✓ Reception of the patient.
- ✓ Patient preparation for any dental treatment.
- ✓ Sterilization and preparation of instruments.
- ✓ Preparation and provision of all necessary facilities such as mouth washes and napkins.
- ✓ Care of patient after treatment.
- ✓ Preparation and mixing of restorative materials.
- ✓ Preparation of the surgery for the next patient.
- ✓ Assistant with x-ray work and the processing mounting of x- rays.
- ✓ Instruction of the patients where necessary in the correct use of the toothbrush.
- ✓ Aftercare of persons who have had general anesthesia.

- **Dental secretary/ receptions:** Non- operatory auxiliary who assist the dentist with his secretarial work and patient reception duties.
- **Dental laboratory technician:** also called dental mechanic a person who fulfills the perceptions provide by dentists regarding extra oral constriction and repair of oral appliance and bridge work(make and repairs dentures and dental appliances, casting of models from impression by dentist, fabrication of denture, splints, orthodontic appliances, inlay, crowns and special trays). Their work is mostly performed in commercial laboratories and not in the dental practice setting.
- **The dental health educator**: give instruction in the prevention of oral /dental diseases.

2. Operating auxiliary:A person who not being a professional is permitted to carry out certain treatment procedures in the mouth under the direction and supervision of a professional. According to revised classification of operatory auxiliary are:

- **The school dental nurse**: this a person who

a. Permitted to diagnose dental disease.

b. Plan and carry out certain specified preventive and treatment of dental caries and periodontal disease in a school children groups.

c. The duties of the school dental nurse are

- ✓ Oral examination.
- ✓ Prophylaxis and topical fluoride application.
- ✓ Advice on dietary and fluoride supplements.
- ✓ Administration of local anesthetic.
- ✓ Cavity preparation and placement of amalgam filling in primary and permanent teeth.
- ✓ Pulp capping.
- ✓ Extraction of primary teeth.
- ✓ Instruction of individual , classroom, teacher and parent about tooth brushing , oral hygiene and dental health education.
- ✓ Referral of patient to private practitioners for more complex services such as extraction of permanent teeth ,orthodontic treatment.

- **The dental therapist:** after training dental therapist for about of a period of 2 years is permitted to carry out certain specified preventive and treatment measures including cavity preparation and restoration of teeth under supervision of dentist. The duties of the dental therapist:
- ✓ Diagnosis of dental caries clinicaly.

- ✓ Cavity preparation of deciduous and permanent teeth.
- ✓ Material handling and restorative skills.
- ✓ Vital pulpatomy and extraction of deciduous teeth under local anesthesia.
- ✓ Taking radiograph under supervision of dentist.

- **The dental hygienist:** this is the person who licensed and registered to practice dental hygiene under the law of the appropriate state, proven, territory or nation. Dental hygienist work under supervision of dentists.The duties of the dental hygienist are

- ✓ Cleaning of mouths and teeth with particular attention to calculus and stain.

- ✓ Topical application of fluoride and sealants and other prophylactic solutions.
- ✓ Screening or preliminary examination of patients (school children)so that may refer to the dentist for treatment.
- ✓ Oral hygiene instruction.
- ✓ Resource work in the dental health.

- ❖ **Expanded function dental auxiliary(EFDA):** they have been referred to expanded function dental assistant, hygienist, techno therapist. Mostly they are assistant and in some cases hygienist with additional training in duties related to the direct dental treatment of patients, through still working under supervision of a dentist.

EFDA performed the following operations:

1. Placing and removing temporary fillings, rubber dam and matrix band.
2. Condensing and carving amalgam restoration in previously prepared teeth.
3. Placing of acrylic restoration in previously prepared teeth, EFDA do not prepare cavities or make decision, but work alongside the dentist who examined and diagnosed the patient and performed treatment plan. EFDA helps him in four handed relationship.

Four handed relationship: the term is given on art of seating both the dentist and the dental assistant in such a way that both are within easy reach of the patient's mouth .the patient is in a fully supine position, the assistant will hand the dentist, particular instrument he needs, in addition to retraction and aspiration. This will decrease the fatigue of dentist and increase efficiency.

Manpower
Can be defined by different ways:
* Is the total number of people who can work to get something done.
* The number of people working or available for work or service.
* All the people who are available to do a particular job or to work in a particular

Dental Manpower

Dentists are concerned with the prevention and control of diseases of the oral cavity and the treatment of unfavorable conditions resulting from these diseases, from trauma or from inherent malformations.

Manpower Surplus
It's a process by which an organization ensures that it has the right number of people and the right kind of people at the right place at the right time, doing things for which they are economically most useful.

Dental Manpower Planning
The process of estimating the number of persons and the kind of knowledge and skills they need to achieve predetermined dental health targets and optimal improvements in dental health of population

STEPS IN MANPOWER PLANNING

1.Analyzing the current manpower inventory.
2.Making future manpower forecasts.
3.Developing employment programs.
4.Design training programs.

Infection control in dentistry

Infection Control : It refers to a comprehensive and systemic program that, when applied prevents the transmission of infectious agents among persons who are in direct or indirect contact with the health care environment.

Why is Infection Control Important in Dentistry?

• Both patients and dental health care personnel (DHCP) can be exposed to pathogens

• Contact with blood, oral and respiratory secretions, and contaminated equipment occurs

• Proper procedures can prevent transmission of infections among patients and DHCP.

The principles of infection control are:

1. Stay healthy: This principle emphasizes the need for dental personnel to be and stay healthy. Strategies include immunizations; post exposure management and medical follow-up by a qualified health care professional; routine hand hygiene procedures; and maintaining hand health.

2. Avoid contact with blood and body fluids: The primary methods to avoid contact with blood and other potentially infectious materials are—handle sharp instruments with care, use safety devices when appropriate, correctly manage occupational exposures to blood, and wear personal protective equipment (PPE) (gloves, protective clothing, and face and eye protection).

3. Limit the spread of contamination: This principle is accomplished by—covering surfaces using surface barriers or cleaning and disinfecting surfaces that are likely to become contaminated; minimizing sprays and splashes to reduce contamination (high volume evacuation, dental dams); and properly disposing of medical waste.

4. Make objects safe for use: The primary methods to make objects safe for use are—cleaning and heat sterilizing patient care items that contact bone, enter previously sterile tissues, or touch mucous membranes before use; monitoring sterilization processes; and following manufacturer’s instructions for use and sterilization.

Transmission Of Infection

The two principle *modes of disease transmission* in which infectious diseases are acquired in dentistry are:

1. Contact

a. Direct contact: Human-human touch. Contact with microorganisms at the source.

b. Indirect contact: Human-object/animal-human touch. Contact with contaminated items such as surfaces especially dental office equipment and/or instruments including contaminated sharps.

2. Droplet Infection

a. Splatter of blood, saliva or nasal secretions onto broken mucosa or skin.

b. Airborne by aerosols of microbes.

The three principle routes of entry of microorganisms into the body are:

a. Inhalation

a. *Direct inhalation*: Inhalation of small particles of moisture (spatter) generated when a person coughs or sneezes, or when water is aerosolized to a fine mist during dental procedures. Risk of disease transmission is usually limited to persons in close proximity to the droplet source.

b. *Indirect inhalation:* Inhalation of particles <5 microns in diameter formed by dehydration of airborne droplets containing microorganisms that can remain suspended in the air for long periods of time or which settle on surfaces and can be readily reintroduced to the environment.

b. Ingestion: Whereby droplets of saliva/blood or particles from instruments are swallowed.

c. Autoinoculation/percutaneous injury: Autoinoculation occurs as a result of the operator touching his/her own mucous membrane or non-intact skin surface with contaminated patient care items or contaminated personal protective barriers. Percutaneous injuries are those that occur as a result of breaking the skin especially with a contaminated sharp instrument.

Components Of Infection Control

1. Immunization
2. Patient screening
3. Hand hygiene
4. Barrier techniques
5. Needle and sharp instrument safety

6. Instrument sterilization and disinfection
7. Surface disinfection and general operatory asepsis
8. Radiographic asepsis
9. Laboratory asepsis
10. Disposal of contaminated wastes

Basic infection control procedures :

1. Personal barrier techniques:

(a)Hand Hygiene

Hand hygiene in health care facilities is the most important aseptic procedure in the prevention of health care associated infections. Hand hygiene significantly reduces microbes on the hands and protects both patients and the dental staff. Handwashing products include plain soap and agents with antimicrobial activity. The wearing of gloves does not replace handwashing, but is an adjunct providing consistent protection from blood-borne pathogens.

Hand hygiene is important because:

• Hands are the most common mode of pathogen transmission
• Reduce spread of antimicrobial resistance
• Prevent health care associated infections

***(b)Gloves* .Gloves used for:**

1. Protect the dental team members from direct contact with patient microbes.

2. Protect patients from contact with microbes on the hands of the dental team members.

Gloves should be:

1. Changed between patients and are not to be washed with detergents at any time.

2. Torn or punctured gloves should be removed as soon as possible .

(c)Masks. Facemasks should be worn to→

1. Prevent spatter from patients' mouths or splashes of contaminated solutions and chemicals from contacting the mucous membranes of the mouth and nose.

2. The reduction in the inhalation of airborne particles .

(d) Eyewear

►The eyes due to limited vascularity and lower immune abilities are susceptible to macroscopic and microscopic injury(risk from the herpes simplex virus and hepatitis .

►Protective eyewear should be available to the patients as well as the dental personnel. The supine position 'renders the patient susceptible to falling objects in the head and neck area.

►All protective eyewear should be cleansed after every appointment. Eyewear should be washed with soap first, then rinsed with water and a surface disinfectant can be used later.

(e) Protective clothing

Protective clothing is the outer layer or covering of garments that would first be contacted by the contaminating droplets, generating sprays, splatter, splashes or spills of body fluids, contaminated solutions or chemicals. This protection can be provided by high neck, long sleeve, knee length garments.

2.Immunization

All dental health care workers should be Immunized by taken a vaccine against the most prevalent infectious disease because they are at risk of infection.

3.Medical history of patient

Complete screening of patient medical history must be taken.

4. Intraoral Barrier Technique

1. Rubber dam . It should be used whenever possible for improved vision and access and to reduce dental personnel's exposure to microorganisms in patient's blood and saliva.

2. Pre-procedural mouthrinse Patient's use of an antimicrobial mouthwash of 0.12 percent chlorhexidine gluconate solution for 30 seconds
prior to intraoral procedures reduces the number of viable oral organisms.

Instrument processing(sterilization of instruments)

Instrument processing involves:

(a) Presoaking **and** cleaning

● Presoaking of contaminated instruments keeps them wet until a thorough cleaning can occur. This procedure prevents blood and saliva from drying on the instruments and facilitates cleaning of instrument which is achieved by;

●Hand scrubbing of contaminated instruments.

●Ultrasonic cleaning is a mechanical cleaning system that reduces handling of contaminated instruments and has been shown to be effective in removing dried blood and saliva.

(b) Packaging

After cleaned instruments have been rinsed and dried, they are to be packaged in functional sets before sterilization.

(c) Sterilization

— Sterilization: It is a process of removing or killing all viable micro-organism including substaintial No. of resistant bacterial spores using physical &chemical procedure.

— Disinfection: It is a process of removing or killing most, but not all, viable organism (e.g bacterial spores) using physical &chemical procedure.

— Sanitization: The process of removing organic debris in order that disinfection can occur.

— Bacteriostatic: An agent that will inhibit increases in the number of bacteria.

— Bactericidal: An agent that will destroy (kill(bacteria, fungi or viruses.

(d) Drying, cooling, storage and distribution of instruments

●Drying→ Instrument packages sterilized in steam become wet and must be allowed to dry before handling so that the packages do not tear.

● Cooling →of warm packages must be done slowly to avoid formation of condensation on the instruments. Using fans to cool down items should also be avoided as, it causes undue circulation of potentially contaminated air around the packs.

●Storage→ sterile instrument packages are stored in a cool, dry, protected area, up off the floor, a few inches away from the walls and ceilings and away from sinks, heat sources, and overhead pipes.

- **Use of disposables For patients**

Using of disposable items to prevent patient-to-patient cross-contamination Numerous disposable items are available in dentistry which include :

Gloves, masks, gowns, surface covers, patient bibs, saliva ejector tips, air water syringe tips, high volume evacuator tips, prophylaxis angles, prophylaxis cups, some instruments, impression trays, fluoride gel trays and high speed hand pieces.

- **Asepsis of Operatory Surfaces**

It is essential to maintain a "disinfected environment" within the working area.

There are two general approaches to surface asepsis :

1. To clean and disinfect contaminated surfaces.

2. To prevent the surface from becoming contaminated by the use of surface covers.

Environmental cleaning Contaminated worktops must be disinfected between patients. The surgery (dental chair, dental unit, worktops and floors) must be thoroughly cleaned at least every day and more frequently if there is obvious contamination. All cleaning agents must be used in accordance with the manufacturer’s instructions.

Treatment needs and demands

Need: Is an important concept in public health. It is used to plan and manage health services including health improvement, resource allocation, and equity. However, need is a multi-faceted concept with no one universal definition.
Demand: Is the expression by a patient or the public of a preference to receive health care related to their perceived needs.
Utilization: Is the actual attendance by members of the public at dental treatment facilities to receive dental care.
Utilization rate : It is expressed as the proportion of a population who attend a dentist within a given time, usually a year or the average number of visits per person made during a year.
Met need: Is measured by utilization data.
Need for care : is defined as the quantity of dental treatment which should be available over a time period for people to be certified dentally healthy. There are various definition of need.

There are four categories of need:

1-Normative need (defined by the professional) Is that which the professional defines as need in any given situation

2-Felt need (Perceived need) This reflects the individual own assessment of his or her requirement for health care. It is equated with want.

3-Expressed need (demand): This is felt need is converted in to action by seeking care .

4-Comparative need, which is assessed by comparing care received by different people with similar characteristics.

- **The methods of assessment of treatment need has been through:**

1-Clinical examination

2-Measuring patient demand for treatment.

3-Survey system to determine oral health status of the population

Factors affecting dental demands:

1-Age: Utilization are lowest in children < 5 years and in person >65 years.

2-Gender: female more than male but in some age and education, male= female
3-Education: Utilization increased with increasing the level of education.

4-Socioeconomic status: higher social class more than low social class. This is because higher social class often related to high income and good educational level.

5-Occupation: Persons in professional occupation visit their dentist more than nonskilled manual worker.

6-Residence: Urban area more than rural area.

Environment and Health

The term of environment involves all the external factors living and non-living, material and non-material which surround human. Proper environmental management is the key to avoid the quarter of all preventable illnesses which are directly caused by environmental factors. The environment affects our health in many ways through exposure to physical, chemical and biological risk factors, and through related changes in our behavior in response to those factors.

Definition of "The Environment "according to Public Health
All that which is external to the individual host. It can be divided into physical, biological, social, and cultural factors, any or all of which can influence health status in populations.
1. **Physical**: Water, air, soil, housing, wastes, radiation, etc.
2. **Biological**: Plant and animal life including bacteria, viruses, insects, and animals.
3. **Social**: Customs, culture, habit, income, occupation, religion, etc.
The purpose of environmental health is to create and maintain ecological conditions that will promote health and thus prevent disease.

Pollution of Water
A more serious aspect of water pollution is that caused by human activity-urbanization and industrialization. The sources of pollution resulting from these are: sewage, industrial waste, agricultural pollutants, and physical pollutants.

Water Related Diseases

Ingestion of contaminated water either directly or through food may affect man's health by causing water related diseases. Such diseases may be classified as:

A. Biological water-borne diseases

1. Those caused by the presence of an infective agent:
a. Viral : Viral hepatitis A, hepatitis E, poliomyelitis
b. Bacterial : Typhoid and paratyphoid fever, bacillary dysentery
c. Protozoal : Amoebiasis, giardiasis
d. Helminthic: Roundworm, threadworm
e. Leptospiral: Weil's disease
2. Those due to the presence of an aquatic host:
a. Snail: Schistosomiasis
b. Cyclops: Guinea worm, fish tapeworm.

B. Chemical

These include industrial and agricultural wastes. Such pollutants include detergents solvents, cyanides, heavy metals, minerals and organic acids, nitrogenous substances, bleaching agents, dyes, pigments, sulfides, ammonia, toxic and biocidal organic compounds of great variety. These pollutants affect health, directly and indirectly by accumulating in foods which are consumed by human beings, e.g. fishes.

Disinfection

Disinfection is accomplished both by filtering out harmful microbes and also by adding disinfectant chemicals in the last step in purifying drinking water. Water is disinfected to kill any pathogens which pass through the filters. Possible pathogens include viruses, bacteria, including Escherichia coli,
Campylobacter and Shigella,

Chlorination

Chlorination is one of the greatest advances in water purification. Chlorine kills pathogenic bacteria, but it has no effect on spores and certain viruses except in high doses. It has limited effectiveness against protozoans that form cysts in water.

Air Pollution

The term Air Pollution signifies the presence in the ambient atmosphere of substances generated by the activities of man in concentrations that interfere with human health, safety or comfort ,or injurious to vegetation and animals and other environmental media resulting in chemicals entering the food chain or being present in drinking water and thereby constituting additional source of human exposure..

Prevention of air pollution:

Scientific groups study the damaging effects on plant, animal and human life. Legislative bodies write laws to control emissions. Educators in schools and universities teach students, beginning at very young ages, about the effects of air pollution.

1. Assessment: is the first step to solve air pollution.
2. Reduce exposure: steps can be undertaken to reduce air pollution. These can be accomplished by regulation of manmade pollution through legislation. Prevention is another key to control air pollution.
3. Adequate ventilation is also a key to control exposure to indoor air pollution. Home and work environments should be monitored for adequate air flow and proper exhaust systems installed.
4. Restricting smoking is an important key to a healthier environment. Cigarette smoke is one of the most dangerous air pollutants.

Dental health education

Health education is defined as any educational activity which aims to achieve a health related goal.

Definition by WHO: any combination of learning experiences designed to help individuals and communities to improve their health, by increasing their knowledge or by influencing their attitude.

Dental health education.
Dental health education is the process of imparting information about dental health. It will help an individual to keep the oral cavity healthy because good oral hygiene helps a person to prevent oral disease such as periodontal diseases, bad breath and other dental problems.

Goal of oral health education
The goal is to improve knowledge that may lead to adoption of desirable oral health behaviors that contribute to better oral health. A basic oral health care program that introduced by World Health Organization for less industrialized countries includes oral health education and emphasizes on the integration of health education with other oral health activities such as provision of preventive, restorative and emergency dental care.

main objectives of health education :

1. *Informing people*: The primary objective is to inform people or provide them with the scientific knowledge about the prevention of disease and promotion of health. This creates an awareness of health needs and helps people to do away with the misconceptions and ignorance they may have about health and disease.
2. *Motivating people*: People must be motivated to change their habits and ways of living as many current health problems are directly related with them for example drug addiction, cigarette smoking, pollution of water, sedentary lifestyles, etc.
3. *Guiding into action*: The people should be encouraged to use judiciously and wisely the health services available to them. They may need help to adopt and maintain healthy lifestyles and practices which may be new to them.

There are three main domains of learning:

1. ***Cognitive:*** Understanding factual knowledge (for example, knowledge that tobacco chewing is linked to development of oral cancer).

2. ***Affective:*** Feelings, emotions and beliefs associated with health (belief that milk teeth are not important).

3. ***Behavioral:*** Skills development (for example, skills required for effective brushing and flossing of teeth).

Setting for oral health education

- Primary care
- Schools and colleges
- Hospitals and clinics
- Preschool education and care
- Local authority services
- Workplace
- Commercial organizations
- Community based initiatives
- Older people's residential homes.

Steps in health education planning

1. Identify needs and priorities.
2. Set aims and objectives.
3. Decide the best way of achieving the aims.
4. Identify resources.
5. Plan evaluation methods.
6. Set an action plan.
7. Evaluation.

Identify needs and priorities

The public health problem must be identified to establish the objectives. The people requiring oral health education also must be identified. Specific group should be selected, in order to ensure health education activity is tailored to their particular needs. In planning effective health education, both professionally defined needs and the target group's concern (felt and expressed needs) should be taken into consideration.

Set aims and objectives

An aim can be set based on the assessed needs of the group specifying the desired change that is planned. One aim could be to improve and maintain the periodontal health through more effective plaque control methods.

Decide the best way of achieving the aims

Once desired aims and objectives have been formulated, the best way of achieving them should be decided. By this stage, the content and method of education should be apparent.

Identify resources

The resources needed and available to implement the program should be identified. In health education, resources may include people's expertise and existing skill, and material such as leaflets or oral hygiene aids.

Plan evaluation methods

A full evaluation of any health education program is a very important element. Evaluation is designed to assess whether the set aims and goals have been achieved. For this, appropriate evaluation measures should be selected.

Set an action plan

The planned action for the program should be initiated.

Evaluation

Evaluation information can be collected both during and at the end of the program to assess the impact of the program.

Pit and fissure sealants

Fissure sealant can be defined as "a material that is introduced into the occlusal pits and fissures of caries susceptible teeth, thus forming a micromechanically or chemically bonded, protective layer cutting access of caries-producing bacteria from their source of nutrients."

Criteria For The Ideal Sealant

1. A viscosity allowing penetration into deep and narrow fissures even in maxillary teeth.
2. Adequate working time.
3. Rapid cure.
4. Good and prolonged adhesion/bonding to enamel.
5. Low sorption and solubility.
6. Resistance to wear.
7. Be compatible with the oral tissues (minimum irritation to tissues).
8. Cariostatic action.

Types of Sealants

A. Based on generation

1. Generation 1 Sealant (photocured via UV light).
2. Generation 2 Sealant (auto or chemically-cured).
3. Generation 3 Sealant (photocured via visible light).
4. Fluoride containing sealants.

B. Based on fillers

1. Unfilled.
2. Filled sealant (fillers increase abrasion resistance, bond strength).

Fillers: glass and quartz particles.

3. Fluoride –Releasing.

C. Based on Color Helps in quick identification for evaluation during maintenance assessment:

1. Clear: Esthetic but difficult to detect in follow-up.
2. Tinted/opaque sealant: easy to detect.

D. BIS-GMA *versus* non BIS-GMA sealant

Procedure of Pit And Fissure Sealant Application

Sealant Placement Guidelines

Step 1: Prepare the Teeth

• Clean the pit and fissure surfaces , Plaque and debris might interfere with the etching process or sealant penetration.
• Utilize a dry toothbrush, prophylaxis cup with pumice or prophylaxis paste, or air abrasion
• Use an explorer to remove any debris in the pit or fissure
• Rinse for 20–30 seconds
• A widening of the fissures with rotary instrumentation is yet another type of fissure conditioning that has been recommended before etchant and sealant application. This is known as the invasive pit and fissure technique.

Step 2: Isolate the Teeth

Adequate isolation is the most critical aspect of the sealant application process. Salivary contamination of a tooth surface during or after acid etching will have a deleterious effect on the ultimate bond between enamel and resin.
• Use cotton rolls, dryi-angles, and/or rubber dam.

Step 3: Dry the Surfaces

• Dry teeth with air for 20–30 seconds
• Check to make sure there is no moisture coming out of air syringe tip.

Step 4: Etch the Surfaces

There are various etchant materials available, but the most frequently used etchant is 37 percent orthophos-phoric acid. This is available as both a liquid solution and a gel. One should always apply the etchant onto all the susceptible pits and fissures of the tooth and extend it up the cuspal inclines well beyond (at least 2 millimeters) the anticipated margin of the sealant:
• Apply etchant as directed by manufacturer , usually between 30 and 60 seconds.
• If using a gel or semi-gel: Apply gel and let stand for the allotted amount of time
• If using a liquid: Continue to apply etchant throughout the etchant time.

Step 5: Rinsing and Drying the Teeth .

• Rinse surfaces for 60 seconds
• Check for effectiveness of etchant by drying with air; surface should appear “chalky white” , If not, repeat etching procedure
• Placement of new cotton rolls and/or dry angles
• Dry teeth with air for 20–30 seconds.

Step 6: Application of Sealant Material

During sealant application, all the susceptible pits and fissures should be sealed for maximum caries protection. The sealant material can be applied to the tooth in a variety of methods. Many sealant kits have their own dispensers, some pre-loaded that directly apply the sealant to the tooth surface:

• Self-curing: Mix equal parts of the two components
• Will polymerize in 60–90 seconds
• Light-curing: Apply with syringe provided by manufacturer
• Apply curing light to material
• Will polymerize in 20–30 seconds.

Step 7: Evaluate the Sealant

the sealant should be visually and tactually inspected for complete coverage and absence of voids or bubbles. Small voids in the sealant can be repaired simply by adding new material to the void and polymerizing.

Step 8: Occlusal Evaluation

• Check occlusion with articulating paper
• Adjustments must be made with filled resins

Step 9: Re-evaluation

• Recall patient for having the sealants evaluated on a six month basis.

Indications for use

A sealant is indicated for children and adults:

1. Who may be at moderate or high risk of developing dental caries, for a variety of reasons.
2. With incipient caries (limited to enamel of pits and fissures).
3. Who have sufficiently erupted permanent teeth with susceptible pits and fissures.
4. Who have existing pits and fissures that are anatomically susceptible pits and fissures.
5. A deep or irregular fissure, fossa, or pit is present, especially if it catches the tip of the explorer (for example, occlusal pits and fissures, buccal pits of mandibular molar, lingual pits of maxillary incisors).
6. The fossa selected for sealant placement is well isolated from another fossa with a restoration present.
7. An intact occlusal surface is present where the contralateral tooth surface is carious or restored.

Contraindications

A sealant is contraindicated if:

1. Patient behavior does not permit use of adequate dry field (isolation) techniques throughout the procedure.
2. There is an open occlusal carious lesion.
3. Caries, particularly proximal lesions, exist on other surfaces of the same tooth (radiographs must be current).
4. A large occlusal restoration is already present.
5. If pits and fissures are well coalesced and self-cleansing.
6. Life-expectancy of primary tooth is limited.
7. When patients is allergic to methacrylate.

Sealant Failure :

The following list describes common technique errors:

1. Contamination may be caused by either saliva or calcium phosphate products as described earlier. The enamel surface must be re-etched if contaminated.

2. Inadequate surface preparation may be caused by improper cleansing prior to applying the etchant and/or the etching process itself.

3. Incomplete or slow mixing of self-cure sealants affects polymerization of the Bis-GMA material, a new mix should be made.

4. Too slow application of the material results in a less viscous (thicker) mix that cannot flow easily into the pits and fissures, causing an incomplete seal. Place material within the time frame recommended by the manufacturer.

5. Air entrapment due to whipping or vigorous mixing can occur during the mixing of self-cured sealants. It is important to replace the caps on the resin bottles since moisture can be lost through evaporation. The result is a less viscous material which does not flow properly.

6. Overextension of the material beyond the conditioned tooth surface results in a weakened sealant in the areas that are overextended. If the sealant margins extend beyond etched tooth structure, those areas will cause increased micro-leakage beneath the sealant and/or fracture of the sealant. The sealant should be replaced, confining the area of placement to etched tooth structure.

7. Outdated materials may not serve as an effective sealant.

Requisites for Sealant Retention

Placement of pit and fissure sealants is technique sensitive. For sealant retention the surface of the tooth must:

1) **have a maximum surface area** Sealants do not bond directly to the teeth. Instead, they are retained mainly by adhesive forces. The surface area is greatly increased by the acid etch, which in turn increases the adhesive potential

2) have deep, irregular pits and fissures (Deep, irregular pits and fissures offer a much more favorable surface contour for sealant retention compared with broad, shallow fossae. The deeper fissures protect the resin sealant from the shear forces occurring as a result of masticatory movements. Of parallel importance is the possibility of caries development increasing as the fissure depth and slope of the inclined planes increases. **Thus, as the potential for caries increases, so does the potential for sealant retention).**

3) be clean

4) **be absolutely dry** at the time of sealant placement and uncontaminated with saliva residue.

Programs of public dental care

Programs of public dental care include:

1. School dental health programs
2. Pregnant women
3. Elderly people
4. Individual require special care
5. Mobile dental clinic

1. School dental health programs

Poor oral health can have a detrimental effect on children's quality of life, their performance at school and their success in later life. School health services contribute to goals of both the education system and the health care system. Coordinated school health programs offer the opportunity to provide the services and knowledge necessary to enable children to be productive learners and to develop the skills to make health decisions for the rest of their lives.

The Four Components of the School Oral Health Program :

1.Education

All children receive oral health education. Practical information to promote healthy behaviors is provided.

2.Fluoride

Weekly fluoride mouth rinse is given to children with parental permission. The mouth rinse is swished for one minute and spit out. It strengthens and protects teeth that are already present in the mouth.

3.Dental Screenings

Dental screenings are conducted by each funded School Oral Health Program at least once during each five years grant cycle. Dental screenings help to identify children who need dental care.

4.Dental Sealants

Dental sealants are thin plastic coatings that are painted into the deep grooves of back teeth. They help to prevent dental decay by sealing grooves that are most likely to decay. School sealant programs are usually conducted by dental hygienists.
program would include:
1. A school water fluoridation project.
2. A carbohydrate control program.
3. Supervised classroom tooth brushing.
4. A dental examination program.
5. A topical fluoride application program.

In schools where the water supply contains adequate amounts of fluoride, the ideal preventive dental program would include:
1. A carbohydrate control program.
2. Supervised classroom tooth brushing.
3. A dental examination program.

1. **Pregnant women**

Pregnancy is a unique period during a woman's life and is characterized by complex physiological changes, which may adversely affect oral health. Preventive, diagnostic, and restorative dental treatment is safe throughout pregnancy and is effective in improving and maintaining oral health. In addition to providing pregnant women with oral health care, educating them about preventing and treating dental caries is critical, both for women's own oral health and for the future oral health of their children. Evidence suggests that most infants and young children acquire caries-causing bacteria from their mothers. Providing pregnant women with counseling to promote healthy oral health behaviors may reduce the transmission of such bacteria from mothers to infants and young children, so that delaying or preventing the onset of caries. For these reasons, it is essential for health professionals to provide pregnant women with appropriate and timely oral health care, which includes oral health education.

2. **Elderly people**

Older peoples' mouths are prone to oral disease and those with natural teeth are more likely to have advanced gum disease (gingivitis or periodontitis). Oral health care for older people is often further complicated by a past dental history including crown and bridge work, partial dentures and implants.

Chronic oral infection can complicate the medical management of general illnesses such as diabetes, chronic heart failure and respiratory diseases.

▪ Poor oral health results in bad breath and affects people's ability to speak, socialize and feel happy with their appearance.

▪ Medications taken by older people often cause dry mouth (xerostomia) which affects speaking, eating and also increases the levels of oral bacteria and infection.

▪ Older people may have a range of health problems or disabilities that affect on their ability to care for their own oral health and may need assistance during their hospital stay as well as follow up care on discharge.

The best ways to maintain a healthy mouth for older people:

1. Brush morning and night.
2. Use fluoride toothpaste on teeth.
3. Use a soft tooth brush on gums, tongue and teeth.
4. Use antibacterial product after lunch (Chlorhexidine product).
5. Keep the mouth moist.
6. Cut down on sugar.

3. Individual require special care

Special Care Dentistry (SCD):

The definition of Special Care Dentistry (SCD) could be as a branch of dentistry that provides oral care services for people with special health care needs (SHCN). It is used in reference to care for individuals with disabilities or those with systemic diseases.

Special Health Care Needs (SHCN)

Special Health Care Needs (SHCN) is defined as any physical, developmental, mental, sensory, behavioral, cognitive, or emotional impairment or limiting condition that requires medical management, health care intervention, and / or use of specialized services or programs.

Health care for individuals with special needs required specialized knowledge acquired by additional training, as well as increased awareness and attention, adaptation, and accommodative measures beyond what are considered routine.

Patients with special health care needs including those with:

• Compromised immunity (Leukemia or other malignancies, human immunodeficiency virus)
• Medically compromised patients
• Cardiac conditions associated with endocarditis
• Mental disability
• Developmental disability
• Physical disability
• Amelogenesis imperfeca
• Dentogenesis imperfect
• Cleft lip / palate
• Oral cancer

5. Mobile Dental Clinic

A Mobile Dental Clinic is a vehicle designed to enable a team of dentists and dentistry providers, to deliver dental care to local communities, allowing your organization to operate beyond the limitations of a fixed facility. A Mobile Dental Clinic may include a variety of equipment and supplies, depending on the client's needs.

Mobile Dental Clinics provide the flexibility to work at various times and locations, connect with outlying and rural communities.

Preventive strategies

• Education of parents to ensure appropriate and regular supervision of daily oral hygiene
• Demonstrating oral hygiene techniques
• Stressing the need to use a fluoridated dentifrice twice daily and to brush and floss daily.
• Use electric or modified tooth brush
• Dietary counseling
• Sealant application
• Use of topical fluoride
• Use of chlorhexidine mouth rinse

Community Dentistry

Dr. Hind Thyab

Dental public health

- Community :a group of people living in the same place or having a particular characteristic in common.
- WHO defines health as ‘a state of complete physical, mental and social wellbeing and not merely the absence of disease or infirmity’
- public health defined as ‘The art and science of preventing disease, prolonging life and promoting physical and mental efficiency, through organized community efforts.
- Dental public health is the science and art of preventing and controlling dental diseases and promoting dental health through organized community efforts.

Aims Of Dental Public Health

- To develop, support and promote programs aimed at the prevention of oral diseases and the improvement of general and oral health.
- To provide expertise and advice on (oral) health promotion programs, suitable for various situations.
- To develop collaboration with Member Associations, non-governmental, governmental and voluntary organizations involved in the promotion of general and oral health. To promote the delivery of best possible oral health care.
- To provide a world forum to exchange knowledge and experience in all aspects of oral health and oral health care.
- To provide a comprehensive information and communication system for making relevant information available to members, the media and governments.

Tools of Dental Public Health

1. Epidemiology
2. Biostatistics
3. Social sciences
4. Principles of administration
5. Preventive dentistry

1. **Epidemiology :** defined as 'the study of the distribution and determinants of health related states or events in specified populations and the application of this study to control health**.**

- *Uses*

1. Causation of disease.
2. Used to describe the health status of the population group .
3. Helps in evaluating effectiveness and efficiency of health services [intervention] .

2. **Biostatistics :** It is the method of collection, organizing, analyzing, tabulating and interpretation of data related to living organisms and human beings.

- *Uses*

1. To test whether the difference between two populations, regarding a particular attribute is real or a chance occurrence.
2. To study the association between two or more attribute in the same population.
3. To evaluate the efficacy of vaccines by controlled studies.
4. To evaluate the progress of public health programs.
5.To define and measure the extent of morbidity and mortality in the community.

3. Social Science It includes sociology, cultural anthropology and psychology. Sociology is the study of human groups.

4. Principles of administration : Administration is defined as "the art and science of guidance, leadership, and control of the efforts of a group of individuals towards some common goal".

5. Preventive dentistry :

Prevention is defined as "actions aimed at eradicating, eliminating or minimizing the impact of diseases and disability. The concept of prevention is best defined in the context of levels, traditionally called, primary, secondary and tertiary prevention".

Stages of Clinical and Public Health Practice

1. Examination/survey

A clinical dentist carries out a thorough and careful examination on the 1st visit of the patient which includes a history and clinical assessment. This helps in future treatment planning for patient. Survey is 1st step in public health practice. It means clinical assessment of the extent and severity of disease in a population. Here the public health dentist examines the population to assess the oral health problem unlike a single patient by clinical dentist.

2. Diagnosis/analysis : A clinical dentist makes a diagnosis of the problem based on the examination. In public health the information collected by survey is analyzed. The analysis of data is done to make the obtained data more meaningful. Statistician and computers aid in compilation of data.

3. Treatment planning/program planning : Treatment planning includes both dentist and patient participation. Dentist's professional judgment of treatment, patient interest in treatment and cost factor etc. are involved. The patient may accept the treatment in full or partially or may reject it completely. In program planning similarly the people may accept the ideal program with enthusiasm or may reject it or accept only a part of it. The decision reflects the community's relative value solving the particular health problem.

4. Informed consent/ethics and planning approval : Informed consent of the patient is taken before starting any treatment. Patient is explained all aspect of treatment planned. Similarly all ethical clearance and approval from all the concerned persons and authorities is taken before implementing a public health program.

5. Treatment/program operation : After taking consent the treatment schedule is arranged. Complex treatment may require services of various specialists for different procedures, which is coordinated by the primary dentist.

6. Payment/finance : Payment for treatment in a clinical setup is informed to the patient and mode of payment acceptable to both the dentist and patient is arranged. Funds for community public health program are arranged by local, state or federal grants. The public health professional is expected to know how to secure and manage the funds. Local or voluntary organization may also contribute towards the program.

7. Evaluation/program appraisal : Patient is evaluated by the dentist regularly during the course of treatment. Recording of initial condition helps to compare with later observations. Similarly data collected in initial surveys serves as a baseline against which effectiveness of an oral health program can be evaluated or assessed. Public health team is accountable to the community for a periodic appraisal of their program.

Functions of Public Health Dentistry

The services provided to the community by public health dentist include:

1. Preventive Services

a. Application of topical fluorides

b. Pit and fissure sealants application

c. Promotion of water fluoridation
d. Defluoridation

2. Public Health Training
a. School teacher training program.
b. Training of the health care worker about dental health and oral hygiene measures.

3. School Dental Health Program
a. Topical fluoride application.
b. School mouth rinsing program.
c. Teaching of oral hygiene methods and importance of dental health to children.
d. Education about safe play areas for children to school authorities.
e. Knowledge about junk foods and effects of cold drinks to children.

4. Dental Public Health Program
a. Examination and treatment of community through dental health program.
b. Screening program for oral cancer.
c. Dental health check up and treatment like extraction, filling, oral prophylaxis of industrial workers through camps.

5. Dental Health Education
a. Education about dental health and its importance to community, industrial workers and social organizations.
b. Imparting knowledge about oral health to expectant mothers.
c. Knowledge about injury to teeth and importance of mouth guards.
d. Education to geriatric population about oral health.
e. Informing people about ill effects of tobacco and smoking.
f. Educating public about methods of prevention of dental diseases like dental caries, periodontal disease and oral cancer.
g. educating care takers about maintenance of oral health in special needs patients.
h. parent counseling for preschool and school children.

6. Program Administration and Promotion
a. Helping the State / Central agency in conducting epidemiological studies regarding oral diseases.
b. Conducting surveys to determine dental needs of the population.
c. Providing dental health knowledge to state agencies or education department.

primary health care and dental public care

Primary health care [PHC]: is essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self -reliance and self -determination.

Components Of Primary Health Care

1. Education is about prevailing health problems and the methods of preventing and controlling them.
2. Promotion of food supply and proper nutrition.
3. Adequate supply of safe water and basic sanitation.
4. Maternal and child health care, including family planning.
5. Immunization against the major infectious diseases.
6. Appropriate treatment of common diseases and injuries.
7. Provision of essential drugs.
8. Prevention and control of locally endemic diseases.

Principles of primary health care:

1-Equitable distribution:
Health services must be shared equally by all people irrespective of their ability to pay and all must have access to health services.

2-Community participation :
Involvement of the community in the planning,
implementation and maintenance of health services,
besides maximum reliance on local resources such as
manpower ,money and materials.

3-Focus on preventive and health promotion The focus of health planners must shift from medical/dental care to prevention and health promotion.

4- Multi-sectoral co-ordination: P.H.C. involves in addition to the health sector ,all related sectors of the community e.g. agriculture ,food industry ,education, housing and other sectors. Oral health can be better integrated into general health programs by including oral health in general health education. For example, smoking effects heart disease, respiratory disease and oral disease.

5- Appropriate technology:
This refers to the technology that is scientifically sound, adaptable to the local needs and acceptable to those who apply it and those for whom it is used.
It refers to avoid using of costly equipment, procedures, techniques when cheaper scientifically valid and acceptable ones are available.
Atraumatic restorative treatment technique offers treatment for caries at low cost where electricity is not available.

Primary dental health care: Dental health may be defined as a state of complete normality and functional efficiency of the teeth and supporting structures and also of the surrounding parts of the oral cavity and of the various structures related to mastication and the maxillofacial complex. Community dental health services: Are those dental health services which have an educative, preventive or curative nature which organized by governments.

P.D.H.C. can be considered under four steps these are:

1-Socially: The community itself must take the principle role in D.H.C. activities . It is the responsibility of dental profession to teach the people that they should not regard dentistry as simply the provision of services to relieve pain and restore function and appearance but they must be motivated to use preventive measures from birth to old age to keep their teeth in a healthy mouth.

Each community must primarily be educated about:

-The benefits of fluoride in reducing dental caries.

-Various oral hygiene measures for removal of dental plaque.

-Correct food habits for children (restriction of eating sweet not more than three times a day and not between snacks).

-Harmful effects of habits such as smoking.

-Early recognition of precancerous and cancerous lesions

-The importance of regular visits to the dentist for routine examination.

2-Technically : Oral health teams must enable both dentist and auxiliaries to guide their community population towards a desired level of oral and general health .

3-Economically: Those responsible for dental health care services must develop systems which utilize the resources available to provide a level of dental health care for everyone . A sound dental health program must be equally spread over the entire population.

4-Politically: Primary dental health care cannot be developed without the full support of national resources . So to become a practical proposition every country must show the political will to examine its health priorities in relation to the social needs of its total population.

Dental Public care: It is that specialized branch of dentistry which deals with delivery of comprehensive dental & oral health care to the masses so as to improve the total dental & oral health of the community as a whole.

Dental care : is the maintenance of healthy teeth and may refer to oral hygiene, the practice of keeping the mouth and teeth clean in order to prevent dental disorders.

- The steps for personnel dental care :

1. Floss at least once per day. ...
2. Brush your teeth twice a day with a soft-bristled toothbrush. ...
3. Use fluoride toothpaste. ...
4. Replace your toothbrush every 3 to 4 months or sooner if needed. ...
5. Eat a healthy diet. ...
6. Avoid sweets and sweetened drinks. ...
7. Do not smoke. ...
8. Keep dentures, retainers, and other appliances clean.

- **Similarities between personal and community health care:**

1. Examination/survey: purpose of survey is to determine the nature and extent of the problem, just as an examination is done when a patient comes to a dental clinic with a complaint.
2. Diagnosis/Analysis: It is the procedure of converting data of survey by meaningful figures or statistics just as a dental clinician uses his examination data to guide him to an accurate diagnosis.
3. Treatment Planning/program planning: Once diagnosis is made one can proceed to make plans for effective treatment. Public health professional would like to have the ideal program plan
4. Treatment/program operation: Execution of the treatment or program once the plan has been made.
5. Payment/ program funding: The patient payment of the dental service can be in the form of cash payment or monthly billing and in community health care the government usually is responsible for funding.
6. Evaluation/ program appraisal: is assessing the effectiveness of the treatment or the health program.

- **Differences between private dental health & public health dentistry**

Differences between personal dental health & public health dentistry		
Characteristic	Personal dental health	Dental public health
1.Target	1. Individual patient	1. Community or group of individuals
2.Visiting	2. The patient comes to the practitioner	2. The public health practitioner goes to the group of individuals
3. Major emphasis	3.Restorative care	3. Preventive care
4. Service provider	4. Dentist alone, sometimes with an assistant	4. Health team professionals
5. Supportive disciplines	5. Psychology	5. Sociology, psychology, education, epidemiology and biostatistics
6. Perspective results	6. Immediate	6. Long term
7. Funding	7. By the patient	7. By government or local authorities

Levels of prevention

There are four levels of preventive care—primordial, primary, secondary, and tertiary care.

Primordial prevention :

It is the prevention of emergence or development of risk factors (beginning with change in social and environmental conditions) in countries or population group in which they have not yet appeared. Individual and mass education is main intervention method in primordial prevention.

Primary Prevention (Pre-pathogenesis) :

It is defined as 'action taken prior to the onset of the disease, which removes the possibility that a disease will even occur'. It is carried out on healthy populations. Primary preventive services are those that prevent the initiation of disease .It may be accomplished by measures designed to promote general health and well-being or by specific protective measures:

1)Health education

2) Environment modification such as safe water, control of insects

3) Nutritional interventions: improvement of nutrition in vulnerable group.

4) Lifestyle and behavioral changes; which favor health

5)Specific protection: include immunization, use of specific nutrition, avoidance of allergens, protection from carcinogens, the use of fluoridated toothpaste and application of pit and fissure sealants.

Secondary prevention (Pathogenesis: Initial Stage of Pathogenesis):

It can be defined as 'actions which halts the progress of a disease at its incipient stage and prevents complications'. The focus of secondary prevention is early disease detection, making it possible to prevent the worsening of the disease and the emergence of symptoms, or to minimize complications and limit disabilities before the disease becomes severe. Secondary prevention ('caution') suggests that the disease has started but can be reversed, and good health can still be achieved through intervening early, when the disease is just starting, and returning the subject to good health. For example when incipient enamel lesions(white spot enamel lesions) can be arrested and reversed using appropriate 'preventive' measures and are reversed before cavities form, other example gingivitis can be reversed before periodontitis sets in, it was well established that frequent oral hygiene reinforcement by dental professionals can prevent caries, gingivitis, and periodontal disease.

Tertiary Prevention (Pathogenesis: Late Stage of Pathogenesis) :

Actions taken when the disease process has advanced beyond its early stages i.e. intervention in late pathogenesis phase. It can be defined as 'all measures available to reduce or limit impairments and disabilities, minimizing suffering caused by existing departures from good health and to promote the patients adjustment to irremediable conditions'. The goal of tertiary prevention is to reduce the negative impact of an already-established disease by restoring function and reducing disease-related complications (prevent further complications or death).Tertiary prevention also aims to improve the quality of life for people with disease.

Community Dentistry

Biostatistics and dental science

Statistics : it's a method of describing , summarizing or displaying a set of data .

Biostatistics : is the branch of statistics responsible for the proper interpretation of scientific data generated in clinical medicine , biology , public health and other health science (the biomedical science) . In the other word , it is the application of statistics in medicine .

Uses of statistics in dentistry :

1. To assess the state of the oral health (define and quantify the disease) in the community and to determine the availability and utilization of dental care facilities .
2. To indicate the basic factors and causation of oral diseases by diagnosing the community and solution to such problems.
3. To plan oral health measures .
4. To determine success or failure of specific oral health care program or measures .
5. For comparison and researches .

Data : Is any information can be collected like : age , gender , height and weight .

Data collection methods : Is a process of collecting information from all the relevant sources to find answers to the research problem , test the hypothesis and evaluate the outcome .

Variables : It is a characteristic that describes a person , place , thing or phenomena that helps to measure changes of disease process which can take different values .

Types of data :

Quantitative data : quantitative or numerical data is information about quantities ; that is , information which can be measured and written down with a number . e.g : height , number of people in the household .

Qualitative data : is information about qualities : information that can actually be measured . Qualitative data is a categorical measurement expressed not in terms of numbers , but rather by mean of categories . e.g: gender , race , color of eyes) .Qualitative data are classified as :

Nominal: Data is in the form of names, labels, or categories. The data cannot be ranked or grouped in any order at all. Examples: Gender, Race, Type of teeth etc.

Ordinal: There can be some sort of ordering but the differences are meaningless, e.g.: Large – Medium – Small; Good – Bad, Malnourished; Normal – Overweight – Obese, or Decayed
– Missing – Filled.

Methods of data collection :

1. **Oral health examination :** when information is needed on the oral disease , this method provides more valid information than health interview . It is indicated by dentists , technicians and investigator .
2. **Interviews (face to face) :** In this method, the interviewer asks questions either face-to-face or through telephone to the respondents. In face-to-face interviews, the interviewer asks a series of questions to the interviewee in person and notes down responses. In case it is not feasible to meet the person, the interviewer can go for a telephonic interview. This form of data collection is suitable when there are only a few respondents. It is too time-consuming and tedious to repeat the same process if there are many participants.
3. **Questionnaire :** A questionnaire is a printed set of questions, either open-ended or closed-ended. The respondents are required to answer based on their knowledge and experience with the issue concerned. The questionnaire is a part of the survey, whereas the questionnaire's end-goal may or may not be a survey.

Sampling methods :

1. Simple random sampling

The simple random sample means that every case of the population has an equal probability of inclusion in sample

2. Systematic sampling

Systematic sampling is where every nth case after a random start is selected. For example, if surveying a sample of consumers, every fifth consumer may be selected from your sample. The advantage of this sampling technique is its simplicity.

3. Stratified random sampling

Stratified sampling is where the population is divided into strata (or subgroups) and a random sample is taken from each subgroup. A subgroup is a natural set of items. Subgroups might be based on company size, gender or occupation (to name but a few). Stratified sampling is often used where there is a great deal of variation within a population. Its purpose is to ensure that every stratum is adequately represented

4. Cluster sampling

Cluster sampling is where the whole population is divided into clusters or groups. Subsequently, a random sample is taken from these clusters, all of which are used in the final sample . Cluster sampling is advantageous for those researchers whose subjects are fragmented over large geographical areas as it saves time and money . The stages to cluster sampling can be summarized as follows:

- Choose cluster grouping for sampling frame, such as type of company or
- geographical region
- Number each of the clusters
- Select sample using random sampling
- Multi-stage sampling

5. Multi-stage sampling

Multi-stage sampling is a process of moving from a broad to a narrow sample, using a step by step process . The main purpose of multi-stage sampling is to select samples which are concentrated in a few geographical regions. Once again, this saves time and money.

Data presentation :

The collection of numerical information often leads to large masses of data which , if they are to be understood , or presented effectively , must be summarized and analyzed in some way . This is the purpose of the subject of statistics .

Various methods are seen in presentation of data but the most common are the tubular and graphical methods .

1. **The tabulation of data :** the presentation of the data in the form of table is called tabulation .

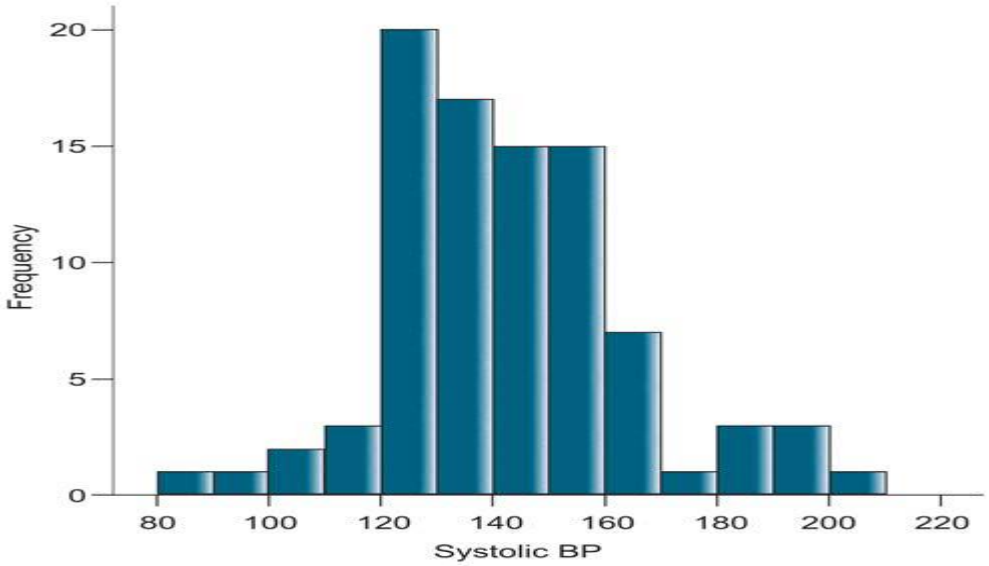
   Frequency Tables : is a table which shows the data arranged into different classes (or categories) and the number of cases (or frequency) which fall into each class .

Gender distribution of survey population

Gender	Number	%
Females	44	58.6
Males	31	41.4
total	75	100

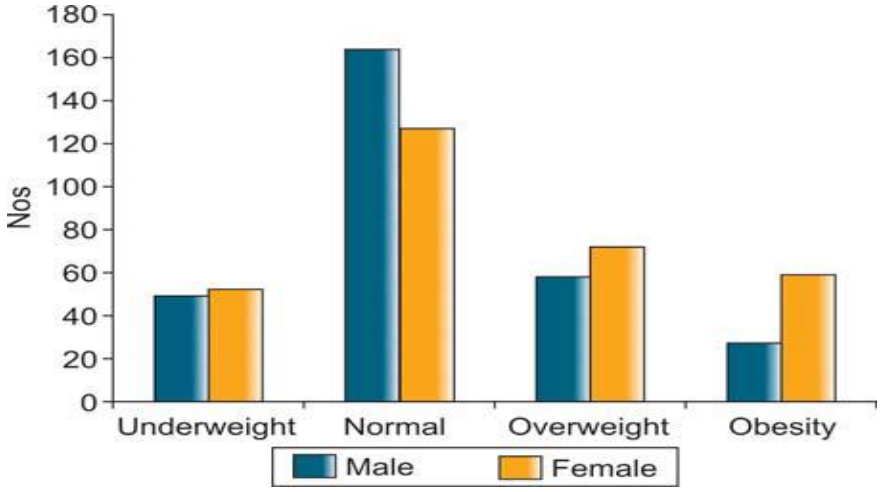
2. **The graphical presentation of the data :** Data can easily be summarized and displayed by a variety of diagrams. The choice of diagram is based on the type of data.

(a) Histogram : A graph for interval or ratio data collapsed into rectangular class which displays the data by using vertical bars of various heights to represent frequencies in each class . This type of graph is used with quantitative data . No gap between the bar , the classes with greater frequencies have taller bar .



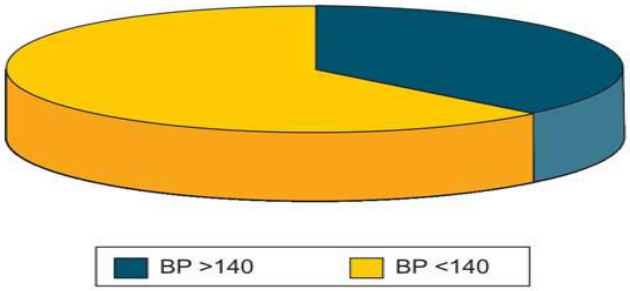
Histogram of systolic blood pressure

(b) Bar graph : A bar chart is similar to a histogram in appearance. However it is used for nominal and ordinal data. Unlike a histogram there are gaps between the bars. The Y axis usually shows the counts or percentage of the total for each group. Two or more variables can be depicted in a multiple bar diagram.



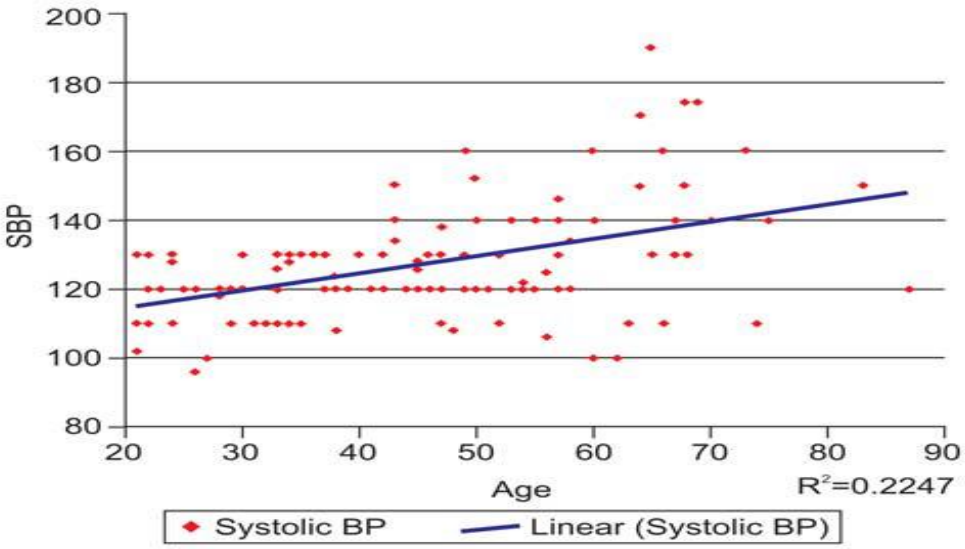
Multiple Bar chart of BMI and Sex in a village

(c) Pie Diagram : Pie charts are used to show the contribution of each item to the whole in which graphical description of data as slices of a pie and the total represents the complete pie . The values are commonly given as a percent or a proportion . It is used for qualitative type of data .



(d)Line Graphs : The frequency is placed along the vertical axis and the class midpoints are placed along the horizontal axis. These points are connected with lines.

(e)Scatter-plots diagram : The scatterplot visualizes a relation (correlation) between two variables X and Y (e.g., weight and height).If the dots cluster round a straight line , it shows evidence of a relationship of a linear nature . If there is no such cluster , it is probable that there is no relationship between the variables .



Scatter plot of systolic blood pressure by age

(f)Statistical maps or dot map: It is used when statistical data refers to graphic or regional distribution of a variables . The areas are shaded with different color and used to present data of varying size .

(g)Pictogram : Popular method of presenting data to those who cannot understand conventional charts . Small pictures or symbols are used to present the data .

Lec 5 : **Community Dentistry** **Dr. Hind Thyab**

Dental caries

Dental caries : It is defined as progressive, irreversible microbial disease of multifactorial nature affecting the calcified tissue of the teeth, characterized by demineralization of the inorganic portion and destruction of the organic portion the tooth.

The Caries Process (Pathogenesis) :

Bacterial Plaque and Acid Production

Plaque on the surface of the tooth consists of a bacterial film that produces acids as a byproduct of its metabolism. To be specific, certain bacteria within the plaque are acidogenic—that is, they produce acids when they metabolize fermentable carbohydrates. These acids can dissolve the calcium phosphate mineral of the tooth enamel or dentine in a process known as demineralization. If this process is not halted or reversed via remineralization (the re deposition of mineral via saliva) it eventually becomes a frank cavity.

Dental caries of the enamel typically is first observed clinically as a so-called "white-spot lesion". The surface layer forms by remineralization. The process of demineralization continues each time there is carbohydrate taken into the mouth that is metabolized by the bacteria. The saliva has numerous roles, including buffering (neutralizing) the acid and remineralization by providing minerals that can replace those dissolved from the tooth during demineralization.

The critical pH value for demineralization varies among individuals, but it is in the approximate range of 5.2 to 5.5. Conversely, tooth remineralization can occur if the pH of the environment adjacent to the tooth is high due to:

(1) lack of substrate for bacterial metabolism; (2) low percentage of cariogenic bacteria in the plaque; (3) elevated secretion rate of saliva; (4) strong buffering capacity of saliva; (5) presence of inorganic ions in saliva; (6) fluoride; and (7) rapid food clearance times. Whether dental caries progresses, stops, or reverses is dependent on a balance between demineralization and remineralization.

Theories of Dental Caries :

1. **The Legend of the Worm**

Ancient Sumerian text known as 'The legend of the worm' gives reference of the tooth decay and tooth pain. It was obtained from the Mesopotamian areas which date back to about 5000 BC. According to the legend, toothache was caused by a worm that drank the blood of teeth and fed on the root of the jaws.

2. **Endogenous Theories**

- **Humoral Theory :**The ancient Greek believed that a person's physical and mental constitution was determined by four elemental humors of the body: blood, phlegm, black bile and yellow bile. An imbalance in these humors is the cause of all diseases including dental caries.
- **Vital Theory :** [Proposed during 18th Century] According to this theory, the tooth decay originated like bone gangrene, from within the tooth itself.

3. **Exogenous Theories**

- **Chemical Theory :** Parmly (1819) proposed that an unidentified "chemical agent" was responsible for caries. According to this theory, teeth are destroyed by the acids formed in the oral cavity by the putrefaction of protein which produced ammonia and was subsequently oxidized to nitric acid. Robertson (1895) proposed that dental decay was caused by acids formed by fermentation of food particles around teeth.
- **Chemoparasitic Theory (Miller) :** It is a blend of chemical and parasitic theory, because it states that caries is caused by acids produced by microorganisms of the mouth. According to this theory, microorganisms of the mouth, by secretion of enzymes or by their own metabolism, degrade fermentable carbohydrate food materials to form acids which demineralize the enamel and the disintegrated enamel is subsequently mechanically removed by force of mastication. Miller summarized his theory as follows.- Dental decay is a chemoparasitic process consisting of two stages- decalcification or softening of the tissue and dissolution of the softened residue**.**
- **Proteolytic Theory (Gottileb- 1947) :** According to this theory, microorganisms invade the organic pathways (lamellae) of the enamel and initiate caries by proteolytic action. Subsequently, the inorganic salts are dissolved by acidogenic bacteria. According to this theory, dental caries results from an initial bacterial and enzymatic proteolytic action on the organic matter of enamel without preliminary demineralization. This causes the release of a variety of complexing agents, such as amino acids, polyphosphates and organic acids which then dissolves the crystalline apatite.

Areas Prone to Dental Caries :

Bacterial plaque is the essential precursor of caries. Hence, sites on the tooth surface which encourage plaque retention and stagnation are particularly prone to progression of lesions. These sites are:

• Enamel in pits and fissures on occlusal surfaces of molars and premolars, buccal pits of molars, and palatal pits of maxillary incisors .

• Tooth surfaces adjacent to dentures and bridges which make cleaning more difficult, thus encouraging plaque stagnation .

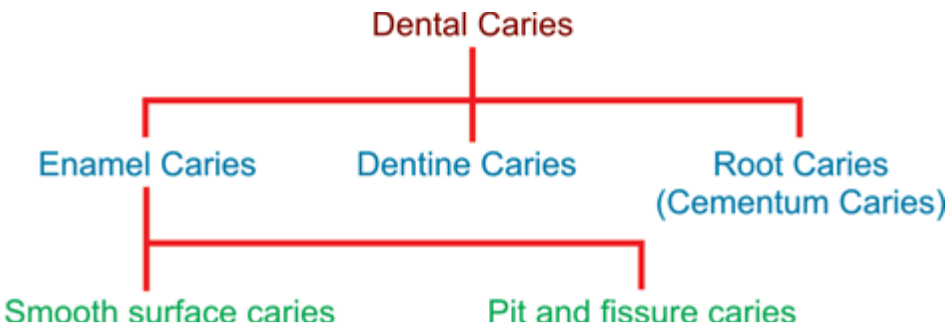
• Approximal enamel smooth surfaces just cervical to the contact point .

• In patients where periodontal disease has resulted in gingival recession, caries occur on the exposed root surface .

• The enamel of the cervical margin of the tooth just coronal to the gingival margin .

• The margins of restorations, particularly those that are deficient or overhanging.

Classification Of Dental Caries :



1. **Enamel caries :**

   a. **Smooth surface caries :**

Incipient caries is the appearance of smooth chalky white area. The overlying enamel surface is smooth, hard and shiny. Early lesion in enamel caries is conical in shape with its apex towards the dentine and base toward the surface of the tooth. Four zones are present with differing translucency. The early enamel lesion consists of four zones of alternating levels of mineralization. It illustrates the dynamic nature of the caries process. The surface zone blocks the passage of calcium ions into the body of the lesion and may have to be removed to allow the lesion to become arrested. Four zones are clearly distinguishable starting from the inner advancing front of the lesion:

1. Translucent zone
2. Dark zone
3. Body of lesion
4. Surface zone

   b. **Pit and Fissure Caries**

Carious lesion starts at both sides of the fissure, not at the base. The enamel is thin in fissures so there is early dentine involvement. The carious lesion forms a triangular or cone-shaped lesion with its apex at the outer surface and base towards the dentinoenamel junction (DEJ).

• Lesion begins beneath plaque, with decalcification of enamel.
• Pit and fissures are often deep, with food stagnation,
• Enamel in the bottom of pit or fissure is very thin, so early dentine involvement frequently occurs.
• Here the caries follows the direction of the enamel rods. In pit and fissure the enamel rods are said to flare laterally at the bottom of the pit and caries is said to follow the path of enamel rods hence a characteristic angular/inverted ‘V’ shaped lesion is formed.
• When reaches DEJ, greater number of dentinal tubules are involved.
• It produces greater cavitation than the smooth surface caries and there is more undermining of enamel.

2. **Caries of The Dentin :**

The caries process in dentine involves the demineralization of the mineral component and breakdown of the organic component of collagen fibers. The caries process in dentine is approximately twice as rapid as in enamel. Spread of caries is more in dentine compared to enamel because of:

1. Decreased calcification (mineralization).
2. Existence of pathways (dentinal tubules).

Advanced carious lesions in dentine consist of two distinct layers having different microscopic and chemical structures. The outer layer is heavily infected by bacteria which are mainly located in the tubule spaces. The collagen fibers are denatured and the organic matrix is not being remineralized. The inner layer is scarcely infected, but affected by plaque acid. It still contains high concentrations of mineral salts and can be remineralized. The initial dentinal changes are known as dentinal sclerosis or transparent dentine. The dentinal sclerosis is due to calcification of dentinal tubules. The change is minimal in progressing caries and more in slow caries. In transmitted light the dentine appear transparent. In reflected light sclerotic dentine appear dark. In advanced lesions tiny liquefaction foci are

formed. In secondary dentine the dentinal tubules are fewer and irregular. Caries spread laterally at the junction of primary and secondary dentine separating both. Various zones are distinguished assuming the shape of triangle with the apex toward the pulp and the base toward the enamel.

3. **Root Caries :**

Root caries can be defined as a lesion which is initiated or extends onto the part of the tooth apical to the cementoenamel junction. The term "primary" as it is used with root caries refers to new dental caries occurring in the absence of a restoration. Secondary (recurrent) root caries refers to caries occurring adjacent to an existing restoration. There is general agreement on this terminology. Root caries most often occurs supragingivally, at or close to (within 2 mm) the cemento-enamel junction. This phenomenon has been attributed to the location of the gingival margin at the time conditions were favorable for caries to occur. The location of root caries has been positively associated with age and gingival recession. This is consistent with the concept that root caries occurs in a location adjacent to the crest of the gingiva where dental plaque accumulates. Root caries occurs predominantly on the proximal (mesial and distal) surfaces, followed by the facial surface. Early root caries tends to be diffused (spread out) and track along the cementoenamel junction or the root surface. More advanced root lesions enlarge toward the pulp.

- **Various Clinical Classification Systems for Caries :**

i. According to location
(*a*) Pit and fissure
(*b*) Smooth surface
(*c*) Root surface
ii. According to clinical appearance
(*a*) Incipient
(*b*) Cavitation
(*c*) Gross destruction
iii. According to rate of disease progression
(*a*) Acute
(*b*) Chronic
(*c*) Arrested
(*d*) Rampant
iv. According to history
(*a*)Primary
(*b*)Secondary or recurrent

Factors Affecting Development Of Dental Caries :

I. Host And Teeth Factor
A. Tooth
I. Composition: Number of studies on the relation of caries to the chemical composition have shown that there was no difference found in the calcium, phosphorus, magnesium and carbonate content of enamel from sound and carious teeth. But there was a significant difference in fluoride content of teeth. It was also noted that surface enamel is more resistant to caries than subsurface enamel. Surface enamel is more highly mineralized and tends to

accumulate greater quantities of fluoride, zinc, lead and iron than the underlying enamel. The surface is lower in carbon dioxide, dissolves at a slower rate in acids and has more organic material than subsurface enamel. These factors contribute
to caries resistance.

II. Morphology: Morphologic features which may pre dispose to the development of caries are the presence of deep, narrow occlusal fissure or buccal or lingual pits. These fissure trap food, bacteria and debris leading to development of caries.

III. Position: Malaligned, out of position, rotated teeth are difficult to clean, favoring the accumulation of food and debris. This may predispose to the development of caries.

B. Saliva

It can be considered as an environmental factor also as teeth are constantly bathed by it. This influences the process of dental caries. Saliva has a flushing action on teeth.

i. Composition: varies from person to person. Saliva is dilute fluid; over 99 percent being made up of water. Proteins (enzymes, immunoglobins and other antibacterial factors, mucous glycoproteins and certain polypeptides) . In Organic Constituents: Major Ions [Sodium, Potassium, and Chloride and Bicarbonate] contribute to osmolarity of saliva. Bicarbonates: Principal buffer in saliva. Thiocyanate: Has antibacterial action. Fluoride: Has anticaries action.

i. Saliva: It has a critical role to play in the development of caries or its prevention. Saliva provides calcium, phosphate, proteins, lipids and antibacterial substances and buffers. Saliva buffering can reverse the low pH in plaque.

ii. Buffering and neutralization: pH of saliva depends on the bicarbonate concentration. Saliva is alkaline and is an effective buffer system. These properties protect the oral tissues against acids and plaque. After eating a sugary food if saliva is stimulated by chewing substances such as wax or sugar free chewing gum, the drop in pH in plaque which would have occurred is reduced or even eliminated. This salivary neutralization and buffering effect markedly reduces the cariogenic potential of foods.

iii. Quantity: Rate of flow of saliva may be an additional factor which helps contribute to caries susceptibility or caries resistance. Mild increase or decrease in flow may be of little significance, near total reduction in salivary flow adversely affects dental caries. There is an inverse relation between salivary flow and dental caries.

II. AGENT FACTORS

A. Microorganisms

The mouth has a diverse resident microbial flora. The normal inhabitants become established early in life. Acid producing bacteria(Streptococcus mutans, Lactobacillus) were found to be associated with the formation of dental caries. Streptococcus mutans is of interest because it has the ability to form an extracellular polymer of glucose, mutans from sucrose, which aids the microorganism in adhering to the enamel surface and in establishing a stable relationship there. L. acidophillus and other acidogenic microorganism in plaque and carious lesion may be capable of producing caries by themselves, or they may be able to act synergistically with Streptococcus mutans in caries initiation. Actinomyces are also among the earliest colonizers of dental surfaces and may constitute up to 27 % of the pioneer bacteria. They have been implicated in root caries, although their role in dental caries initiation and progression is not well understood.

B. Dental Plaque

Bacterial plaque is a dense non-mineralized, highly organized mass of bacterial colonies in a gel-like intermicrobial, enclosed matrix or slime layer. It is a transparent film that can be *supragingival*, coronal to the gingival margin on the clinical crown of the tooth and *subsgingival,* apical to the margin of the gingiva.

III. Environmental Factors

A. Diet

According to acidogenic or chemoparasitic theory, dental caries occurs when acid is produced by bacteria in dental plaque when refined carbohydrates are eaten. The presence of refined carbohydrate as sugar is essential for the majority of caries development and sucrose is the most cariogenic of all sugars. In human consumption, sucrose accounts for 60 percent of all sugars eaten.

b. Oral Hygiene

Inverse relationship has been seen between oral hygiene and dental caries. Poor oral hygiene increases the rate of dental caries.

c. Fluoride

Fluoride in water and soil decreases incidence of dental caries.

Methods Of Prevention Of Dental Caries

1. Increase The Resistance Of The Teeth

A. Fluorides

Widespread use of multiple forms of fluoride is mainly responsible for the marked decrease in caries throughout the world.

- Systemic Use of Fluoride

1. Community water fluoridation
2. Milk and salt fluoridation
3. Fluoride supplementation in the form of tablets and lozenges
4. Consuming a fluoride-rich diet such as tea, fish, etc.

- Topical

1. Use of fluoridated toothpaste
2. Use of fluoride mouthwash
3. Use of fluoride varnishes (in-office application, longer duration of action, high fluoride content)
4. Professionally applied solution
5. Fluoride gels

B. Sealants : Pit and fissure sealants are adhesive resins which help to seal these pits and fissure and prevents dental caries.

C. Saliva Substitutes Containing Fluoride : A saliva substitute may be helpful and sometimes necessary in patients with practically no saliva production due to, e.g. radiation towards the head and neck region, medication, diseases in saliva glands or other reasons that may result in long-lasting oral dryness.

2. Combat Caries-Inducing Microorganisms

This includes combating the microbial plaque by physical and chemical methods.

A. Physical Methods (Removal of Plaque)

a. Tooth brushing

b. Use of dentifrices

c. Prophylaxis by dentist

e. Use of dental floss/tooth pick

B. Chemical Methods

a. These include the use of fluoride-containing toothpaste.

b. Mouth rinses — chlorhexidine 0.2 percent (0.12% in USA).

c. Use of povidone–iodine mouthwash.

C. Caries Vaccine : The development of a vaccine against dental caries involves identification of appropriate antigens of mutans streptococci against which protective immune responses can be mounted, and the selection of a method of immunization that will generate sustained levels of salivary antibodies.

Epidemiology of malocclusion

Occlusion : Is defined as the anatomic alignment of teeth and their relationship to the rest of the masticatory system.

Normal occlusion : This refers to an occlusion that deviates in one or more ways from ideal yet it is well adopted to that particular environment, is esthetic and shows no pathologic manifestations or dysfunction. Also it is defined as normal occlusion as the occlusion which is within the standard deviation from the ideal.

Ideal occlusion : It is a preconceived theoretical concept of occlusal structural and functional relationships that includes idealized principles and characteristics that an occlusion should have. Also it is defined as ideal occlusion as „a hypothetical standard of occlusion based on morphology of the teeth.

The alignment and occlusion of the dentition are extremely important in masticatory function. The basic activities of chewing, swallowing, and speaking depend greatly not only on the position of teeth in the dental arches but also on the relationship of opposing teeth as they are brought into occlusion .

Malocclusion

The condition in which dental structure are not in acceptable equilibrium with each other or with the facial structures and/or the cranium, thus interfering with or posing a potential threat to the normal tissue development and maintenance, effective function or a psychological behavior problem.

Prevalence Of Malocclusion

- The aim of epidemiologic studies of malocclusion is to describe and analyze the prevalence and distribution of malocclusion in various populations, the ultimate goal being to identify etiologic factors.
- A further aim is to contribute to the solution of the public health problems concerning assessment of need for orthodontic treatment and organization of orthodontic services.
- At an early point, it was realized that due to the complexity of malocclusion, epidemiologic studies had to be based on some kind of

classification. Angle's classification is the only one among several typologic classifications which has gained wide ground in the epidemiology of malocclusion.

- Different surveys have reported data on the prevalence of different types of malocclusion. Most of the studies have been carried out in Europe and North America and a few in Asia. Most of these studies differ in their examination criteria, sampling techniques, age, sex, and availability of radiographs/study casts and examiner accuracy leading to difficulty in direct comparisons.

- **Classification Of Malocclusion**

malocclusions can be broadly divided into three types:

• Individual tooth malpositions.

• Malrelationship of the dental arches or dentoalveolar segments.

• Skeletal malrelationships.

These three can exist individually in a patient or in combination involving each other, depending upon where the fault lies in the individual dental arch or the dentoalveolar segments or the underlying skeletal structure.

Angle's classification of malocclusion :

Class I : most common (maxillary mesiobuccal cusp located in mesiobuccal development groove of the mandibular first molar) .

Class II : posterior positioning of the mandible to maxilla .

Class III : anterior positioning of the mandible to maxilla .

Etiological factor of malocclusion :

- **General Factors**

1. Heredity.
2. Congenital.
3. Environment:

a. Pre-natal (trauma, material diet, German measles, material maternal metabolism, etc.).

b. Postnatal (birth injury, cerebral palsy, TMJ injury)

4. Pre-disposing metabolic climate and disease:

a. Endocrine imbalance.

b. Metabolic disturbances.
c. Infectious diseases.
5. Dietary problems (nutritional deficiency)
6. Abnormal pressure habits and functional aberrations:
a. Abnormal sucking.
b. Thumb and finger sucking.
c. Tongue thrust (the condition in which the tongue contact any teeth anterior to the molars during swallowing) and tongue sucking.
d. Lip and nail biting.
e. Abnormal swallowing habits (improper deglutition).
f. Speech defects.
g. Respiratory abnormalities (mouth breathing etc.).
h. Tonsils and adenoids.
i. Psychogenic tics and bruxism.
8. Trauma and accidents.

- **Local Factors**

1. Anomalies of number: Supernumerary teeth, Missing teeth (congenital absence or loss due to accidents, caries, etc.).
2. Anomalies of tooth size.
3. Anomalies of tooth shape.
4. Abnormal labial frenum: mucosal barriers.
5. Premature loss.
6. Prolonged retention.
7. Delayed eruption of permanent teeth.
8. Abnormal eruptive path.
9. Ankylosis.
10. Dental caries.
11. Improper dental restorations.

Untreated Malocclusions :

Untreated malocclusions can cause the following:
• Further derangement in the arrangement of teeth
• Lips, tongue, or cheeks that contact biting surfaces due to poor tooth alignment might cause frequent abrasions or cuts .
• Inefficient or uncomfortable biting, chewing, and digestion
• Speech impairments
• Crowded teeth are hard to clean, leading to cavities and gum disease
• Abnormal wear of tooth surfaces might lead to sensitivity or chipping
• Loosening, chipping or fracturing of a malaligned tooth that is overstrained
• Premature loss of teeth
• Injury to a protruding upper incisor
• Thinning of bone and receding gums associated with roots of very crowded or protruded teeth
• Accelerated gum disease and bone loss specially in crowded dentitions
• Temporomandibular joint (TMJ) dysfunction
• Adverse effects on facial development and appearance
• Psychological complexes
• Need for surgery.

Epidemiology of oral cancer

- Cancer is one of the major threats to public health in the developed world and increasingly in the developing world. In developed countries cancer is the second most common cause of death.
- Oropharyngeal cancer is more common in developing countries than developed countries.
- The prevalence of oral cancer is particularly high among men, the eighth most common cancer worldwide.
- Incidence rates for oral cancer vary in men from 1 to 10 cases per 1,00,000 population in many countries.
- Oral cancer term includes cancers of lip, tongue, buccal mucosa, floor of mouth and pharynx.
- Cancer of the oral cavity comprises approximately 30 percent of head and neck region tumors and 3 percent of all cancers in the United States.

Incidence

The disease is almost twice as common in men and the majority of malignancies [90–95%] are squamous cell carcinomas. The incidence increases with age. There is great variation, however, in sex incidence between various sites in the oral cavity.

Type

the majority of malignancies [90–95%] are squamous cell carcinomas. There is great variation, however, in sex incidence between various sites in the oral cavity.

Etiology of oral cancer

1. Established risk factors:

a. Smoking tobacco: It is addictive. Smoked tobacco contains thousands of chemical compounds. Many of these compounds are not only irritants and toxin, but they are also carcinogens.

Constituents Of Tobacco Smoke

Tobacco smoke is a complex mixture of several thousand chemical compounds

a. Nicotine

Nicotine is among the most toxic of all poisons and acts with great speed (**nitrosamines, which are potent carcinogens component)**. It is the pharmacological agent in the tobacco smoke that causes addiction among smokers. The addictive effect of nicotine is linked to its capacity to trigger the release of dopamine—a chemical in the brain that is associated with the feelings of pleasure.

b. Tar

Tar is a sticky brown substance which can stain smokers' fingers and teeth yellow brown. It also stains the lung tissue.Benzopyrene as a carcinogen is a prominent polycyclic aromatic hydrocarbon found in tar.

c. Carbon Monoxide (CO)

Carbon monoxide is a colorless, odorless, poisonous gas. Carbon monoxide interferes with uptake of oxygen in the lungs and with its release from the blood to the tissues that need it.

b. ALCOHOL

By 1988 International Agency for Research on Cancer accepted both tobacco smoking and alcohol consumption as independent risk factors for oral cancer. Combined effect of alcohol and tobacco is greater than the sum of the two effects independently.

c. MOUTHWASH USE

Mouthwashes with high alcohol content [25% or higher] may increase risk of oral cancer. Risks generally increased in proportion tofrequency and duration of mouthwash use.

Predisposing factors

A. Vitamins And Essential Minerals

Vitamin A: Risk of oral cancer has been inversely associated with consumption of vitamin A, and also consumption of fruits and vegetables in many studies.

Vitamin C: There is a tenous association of vitamin 'C' with a protective effect against oral, pharyngeal and esophageal cancer.

Vitamin E: Vitamin E like β-carotene is anti-oxidant. Higher serum vitamin levels appear to be associated with decreased risk of oral cancer. Vitamin E use may have some protective effect against leukoplakia and carcinomas.

B. Occupation

Thereis increased risk for oral cancer and pharyngeal cancer for workers exposed to formaldehyde.There is higher incidence of lip cancer in outdoor and rural population than in office workers or urban population. This may be due to exposure to sunlight and UV radiation.

C. Chemical Agents

Exposure to chemical agents like aromatic amines, Alfa toxins, polycyclic aromatic hydrocarbons, etc. is predisposing factor for oral cancer.

D. Viral Infection

Infection with viruses: There are several viruses that seem to increase the risk for oral cancer such as Human papillomaviruses (HPV) , Epstein-Barr virus is a virus and Herpes simplex viruses cause a viral infection.

Trauma

Many human cases are described of an oral cancer at the site of chronic trauma arising from a broken tooth, a denture clasp, or an ill-fitting denture flange or excrescence. Studies indicate that denture wearing per se is not a risk factor, but that chronic ulceration from an unsatisfactory appliance may promote a neoplasm in the presence of other risk factors.

Pathogenesis

The most common type of oral cancer is epidermoid carcinoma (squamous cell carcinoma). Epidermoid carcinoma originates in abnormal mucosa as either leukoplakia, erythroplakia or speckled leukoplakia. This disease most commonly begins in a leukoplakic lesion which can be smooth or rough, flat or elevated, ulcerated or intact. Leukoplakia is manifested histologically by a thickening of the mucosa.

Potentially Malignant Lesions

Main potentially malignant lesion is:

• Leukoplakia
• Erythroplakia
• Erosive lichen planus
• Submucosal fibrosis.

Such lesion as leukoplakia and erythroplakia can precede the development of malignancies. However the rate of malignant transformation is very low 2–6 percent.

The Importance Of Early Detection

• Early detection saves lives. With early detection and timely treatment, deaths from oral cancer could be dramatically reduced
• The five-year survival rate for those with localized disease at diagnosis is 81 percent compared with only 30 percent for those whose cancer has spread to other parts of the body.

Levels Of Prevention For Oral Cancer

Primary Prevention

1. Avoid tobacco and alcohol use.
2. Avoid betel nut chewing.
3. Avoid smoking.
4. Avoid exposure to sun.
5. Ensure a healthy diet free from vitamin and nutritional deficiency.
6. Dentists may be able to influence politicians and communities to adopt relevant policies, but more importantly they can directly influence smokers to stop using tobacco, reduce alcohol consumption and improve their diet.

Secondary Prevention

• Screening of high risk groups
• Biopsy: any suspicious oral mucosal lesion including any non-healing ulcer [more than two weeks] must be biopsied. Biopsy should be sufficiently large to include enough suspect and apparently normal tissues for correct diagnosis.

Tertiary Prevention

• Surgery, radiotherapy, and chemotherapy.

• In order to stop the recurrence and spread of oral cancers, dentists and other health specialists should work together to provide multi-disciplinary support for patients.

• Treated patients may still have dental needs which dentists should monitor to maintain life quality. There may be special needs as well.

• Prevention of caries by topical fluoride application, dietary advice.

• Management of a dry mouth, and prosthetic rehabilitation
following surgery and radiation therapy.

Rehabilitation after Oral Cancer

Rehabilitation may vary from person-to-person depending on the type of oral cancer treatment, and the location and extent of the cancer. Rehabilitation may include:

• ***Dietary counseling:*** Many patients recovering from oral cancer surgery have difficulty eating, so it is often recommended that they eat small meals consisting of soft, moist foods.

• ***Surgery:*** Some patients may benefit from reconstructive or plastic surgery to restore the bones or tissues of the mouth, returning a more normal appearance.

• ***Prosthesis:*** If reconstructive or plastic surgery is not an option, patients may get benefit from dental or facial-part prosthesis to restore a more normal appearance. Special training may be needed to learn to use a prosthetic device.

• ***Speech therapy:*** If a patient experiences difficulty in speaking following oral cancer treatment, speech therapy may help the patient relearn the process.

Fluoride in dentistry

Fluorine is an electronegative, naturally occurring element. It is the most reactive of all chemical elements . The reduced form of fluorine (or its ionic form) is called as fluoride .Fluorine cannot occur in nature in its elemental form, but only as a fluoride ion which continues to play a vital role in prevention of dental caries . The caries-preventive effect of fluoride has been known since the 1930s, when the differences in caries prevalence between communities were attributed to naturally occurring fluoride levels in the drinking water. Scientists have discovered that fluoride helps to protect teeth from dental decay; most of the work in caries prevention has been based on some type of fluoride use. Due to its safety, efficacy and cost-effectiveness in preventing caries the purpose of fluorides in various forms thus remains cornerstone of most caries prevention programs.

Sources of Fluoride

1- Ground waters: Rain water, Sea water &river water
2- Atmosphere: fluoride- containing soils and gas, underground coal fires and volcanic activities
3- Food: present to some extent in nearly all foods. Certain foods contain more F than others, e.g. tea & some seafoods.
4- Drugs & fluoride-containing dental products.
5- Pollution: in vicinity of industries involved in production of aluminum from cryolit & phosphate fertilizers.

Community water fluoridation:

Water fluoridation considered as one of the "ten greatest public health achievements of the 20th century ."It is the controlled addition of fluoride to a public water supply for optimal dental health which effectively prevents caries. It is the best method of delivering fluoride on a population basis.

History:

- The history of community water fluoridation traced back to 1901 Dr. Frederick McKay, a dentist noticed that some of his patients in Colorado springs have permanent stain on their teeth. He named these stains as “mottled enamel”
which were intrinsic, or incorporated into the enamel structure, and they were limited to a subgroup of patients who had either been born in Colorado Springs or moved there at a very young age.
-1916 Dr. McKay & Dr. Black conducted studies on individual in 26 communities in USA & concluded that an “unidentified factor” present in the water was responsible for mottling of enamel. Dr. McKay found that these mottled enamel cases are singularly free from caries.”
-McKay had identified the etiologic agent which is the high level of fluoride in
drinking water.

- Dean and co-workers conducted a survey on 21 cities to establish the relationship between mottled enamel which replaced by the term dental fluorosis and the level of fluoride in the water supply.

The three types of fluoride that are used to fluoridate water are:
- Sodium fluoride,
-Sodium fluorosilicate
-Fluorosilicic acid.
The optimum level of fluoride in the communal water supply varies depending on the temperature and geographic location, its range from 0.7-1.0 ppm. This concentration allows minimum dental fluorosis with maximum caries reduction.
Community water fluoridation is safe and cost-effective and should be introduced and maintained wherever it is socially acceptable and feasible.

Pre-eruptive Systemic Effects of fluoride :

Fluoride is absorbed through the gastrointestinal system. The rate and degree of absorption depend on the solubility of the source and the amount ingested at a given time. Once absorbed into the bloodstream, fluoride is either deposited into bones and developing teeth or excreted in the urine. The major sources of systemic fluoride are water fluoridation and dietary supplements; food sources are a lesser but potentially important source. During tooth development, fluoride is incorporated into the developing tooth's mineralized structure. Although this is no longer believed to be the most important reason for the effect of fluoride in dental caries, the presence of fluoride in the dental enamel probably increases resistance to demineralization when the tooth surface is exposed to organic acids.
Systemic fluoride may enhance the resistance of the tooth by way of:
1. An alteration in tooth morphology, and
2. A conversion of the hydroxyapatite mineral to a fluoridated state with an attendant reduction in solubility and an enhancement of the remineralization phase of the caries process.

Mechanism of action of fluoride :

1 . Increased enamel resistance
Fluoride reduces the solubility of dental enamel by both systemic and topical action. Fluoride ingested prior to tooth eruption enhances the development of fluorapatite at the enamel surface and that this fluorapatite is resistant to the demineralizing acids that initiate the carious process.

2. Inhibiting Demineralization
If fluoride is present in the solution surrounding the crystals (enamel fluid) it is adsorbed strongly to the surface of carbonated apatite crystals acting as a potent protection mechanism against acid dissolution of the crystal surface **.** When the entire crystal surface is covered by adsorbed fluoride (fluorapatite), it will not dissolve upon a pH fall caused by bacterial-derived acids. significant protection could be obtained if all crystals along the acid ions diffusion pathway are coated with fluorapatite.

3. Increased rate of post-eruptive maturation
At the time of tooth eruption the enamel is not completely calcified and undergoes a post-eruptive period of approximately 2 years during which enamel calcification continues.
Throughout this period-period of enamel maturation' there is continuous accumulation of fluoride as well as other elements in the superficial part of enamel.

4. Enhancing remineralization
As the saliva flows over the plaque and its components neutralize the acid, raising the pH, demineralization is stopped and reversed. The saliva is supersaturated with calcium and phosphate, which can drive mineral back into the tooth. These processes constitute remineralization—the replacement of mineral in the partially demineralized regions of the carious lesion of enamel or dentine (including the tooth root). Fluoride enhances remineralization by adsorbing to the crystal surface and attracting calcium ions, followed by phosphate ions, leading to new mineral formation.

4. anti-bacterial action
fluoride ions within the cell interfere with the glycolitic enzyme (enolase) activity , Thus, fluoride effectively inhibits the carbohydrate metabolism of acidogenic oral bacteria, including the uptake of sugars. Fluoride interferes with oral bacteria in two ways , in low concentration , fluoride is bacteriostatic and in high concentration , fluoride is bactericidal .

Types of fluoride

A- Systemic fluoride : Its benefit in pre-and post-eruptive phase .

1-Communal water fluoridation : Fluoridations is the controlled adjustment of a fluoride compound to a public water supply in order to bring the fluoride concentration up to a level which effectively prevents caries.

2- Alternative methods for C.W. F.:

- School water fluoridation.
- Home water fluoridation.
- Fluoridated tablets.
- Fluoridated salts.
- Fluoridated milk.

B- Topical fluoride: The term topical fluoride therapy refers to the use of systems containing relatively large concentrations of fluoride that are applied locally or topically, to the erupted tooth surface to prevent the formation of dental caries.Its benefit in post eruptive phase .

1. Self applied:

- Dentifrices.
- Fluoridated mouth rinse.
- Fluoridated gel.

2. Professional fl. application: It was seen that when fluoride was applied to teeth, it gets deposited in the outer enamel, making it more resistant to dissolution by acids. Topical

fluoride applications are indicated for patients with active smooth surface caries and those patients in high caries risk groups , this includes special patient groups, such as those undergoing orthodontic treatment, in high-risk groups to reduce tooth sensitivity , active decay , patients undergoing head and neck irradiation (decreased salivary flow) .Topical fluoride available in the form of solutions, gel, foam, varnishes, prophylactic paste or pumice.

Many types of fluoridated agent used, mainly:

- ❖ Sodium fluoride (NaF).
- ❖ Stannous fluoride (SnF2).
- ❖ Acidulated phosphate fluoride.
- ❖ Zirconium fluoride.
- ❖ Titanium fluoride.
- ❖ Amine fluoride.

Choice of fluoride type and dose depends on:

- current levels of fluoride intake.
-caries status.
-age of subjects in the area.

In general, fluoride has many effects in relation to caries reduction(anti-caries effect)these include:

1-Decrease solubility of enamel in acid by converting hydroxyapatite into less soluble Fluorhydroxyapatite /fluorapatite.
2- Enhance remineralization of enamel in areas that have been demineralized by acids.
3- Antibacterial action: Bactericidal in high conc. & bacteriostatic in low conc.
Fluoride affects oral bacteria and dental plaque ecology. It inhibits bacterial adsorption & decreases acid production of plaque bacteria (inhibiting glycolysis in microorganisms).
4- Improve tooth morphology making them more self-cleansings**.**

Metabolism of fluoride

When F is ingested, the absorption occurs mainly in the stomach. F concentration in the blood reaches a peak after about 30 minutes, and returns to the usual level after 11- 15 h. about 99% of F is associated with calcified tissue (bone & teeth). F also can be absorbed following inhalation and through the skin. The main route of F excretion is via the kidney.

Side effects of fluoride:

Fluoride is a hazardous substance when large doses are taken acutely or when lower doses are taken chronically, it could cause:

o Dental fluorosis.
o Reversible gastric disturbances.
o Skeletal fluorosis.
o Death.

Dental Fluorosis

Hypo mineralization of enamel results from prolonged ingestion of fluoride during the period of tooth development.

Clinically: Opaque white patches in the enamel which may become striated, mottled, pitted or stained yellow to dark brown.
There are many indices for assessment of dental fluorosis, one of these is Dean's Dental Fluorosis Index which was developed by Dean in.

Prevention of dental fluorosis

Alternative water supply with optimal or suboptimal F levels is the only effective preventive measure in area with high level of F in drinking water. If this not possible, the available drinking water can be defluridated

De fluoridation of water: Is the downward adjustment of F ion concentration in public water supply to be maintained at 1 ppm by weight.
